Second Edition (February 1975)

This edition replaces the previous edition (numbered GC26-3838-0) and makes that edition obsolete.

This edition applies both to Release 4 of OS/VS1 and to Release 3 of OS/VS2, and to all subsequent releases of either system unless otherwise indicated in new editions or technical newsletters. (Information on enhanced VSAM under OS/VS2 is only for planning purposes until the availability of the OS/VS VSAM Independent Component Release for Release 3 of that system.)

Significant system changes are summarized under “Summary of Amendments” following the list of figures. In addition, miscellaneous editorial and technical changes applicable to either or both of OS/VS1 and OS/VS2 have been made throughout the publication. Each technical change is marked by a vertical line to the left of the change; there are no significant changes for Release 3 of OS/VS2.

Information in this publication is subject to significant change. Any such changes will be published in new editions or technical newsletters. Before using the publication, consult the latest Virtual Storage Supplement (to IBM System/360 and System/370 Bibliography), GC20-0001, and the technical newsletters that amend the bibliography, to learn which editions and technical newsletters are applicable and current.

Requests for copies of IBM publications should be made to the IBM branch office that serves you.

Forms for readers’ comments are provided at the back of the publication. If the forms have been removed, comments may be addressed to IBM Corporation, System Development Division, LDF Publishing—Department J04, 1501 California Avenue, Palo Alto, California 94304. All comments and suggestions become the property of IBM.

This publication describes the use of VSAM (Virtual Storage Access Method), an access method of OS/VS (Operating System/Virtual Storage). It is intended for Assembler language programmers who intend to use VSAM macro instructions to process data and for higher-level language programmers who may want to use ISAM programs to process data. The publication has the following major divisions:

- "Introduction," which introduces basic VSAM concepts that the reader needs in order to use VSAM.
- "Opening and Closing a Data Set," which describes job control language and the OPEN and CLOSE macros.
- "Control Block Macros," which describes VSAM macros used to construct the control blocks required to open and use data sets and exit routines, and to modify, test, and display fields in control blocks.
- "Request Macros," which describes macros used to retrieve, store, update, and erase records, and to suspend processing and terminate requests.
- "Using ISAM Programming with VSAM," which describes how data sets can be converted to VSAM's format and can be processed using an ISAM processing program.
- "User-Written Exit Routines," which describes how to write the exit routines that can be used with VSAM.
- "Appendix A: Summary of Macros," which summarizes, for ease of reference, the format of the macros used to communicate with VSAM.
- "Appendix B: List, Execute, and Generate Forms of GENCB, MODCB, SHOWCB, and TESTCB," which explains how to code reentrant programs with the macros that generate, modify, test, and display control blocks at execution.
- "Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB," which gives all of the ways of coding operands in the macros that generate, modify, test, and display control blocks at program execution time.
- "Glossary," which defines VSAM terms.
- "Index," which is a subject index to this publication.

**Conventions Used in the Publication**

The conventions used in this publication for writing the macro and JCL statements indicate whether an operand is optional, how to specify the value for an operand, and how to punctuate a macro or statement. The conventions are:

- Expressions enclosed in brackets, [], are optional.
- Items separated by an OR sign, |, and enclosed in braces, {}, are alternatives, only one of which may be specified.
- An underlined item, item, is the default when you don't specify anything for an operand.
- Ellipses, ..., indicate that you may repeat the preceding item.
Capitalized **BOLD** expressions, parentheses, commas, and equal signs must be entered as shown, except that, unless otherwise noted, parentheses aren't required if you specify only one item.

Lowercase *italic* expressions are variables for which you may specify one of a number of expressions.

**VSAM and Access Method Services Publications**

The VSAM and Access Method Services libraries have been revised and expanded. Books listed below that are designated *OS/VS1* apply only to Release 4 of OS/VS1. Books designated *OS/VS2* apply only to Release 3 of OS/VS2. Four new books designated *OS/VS2 Independent Component* apply only to the release of VSAM as an independent component for use with Release 3 of OS/VS2. The shared book applies to OS/VS1, OS/VS2, and the independent component.

This publication makes frequent references to the VSAM and Access Method Services publications. Rather than list all the titles at each reference point, the text will refer to the *appropriate publication* for the particular subject.

The VSAM and Access Method Services publications are:

- **OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications**, GC26-3819, which provides information about advanced applications of VSAM. The topics, which do not apply to normal use of VSAM, include: gaining access to control intervals; I/O buffering; constructing parameter lists for the macros that generate, modify, and examine control blocks at execution; processing the index as data; sharing resources; and displaying fields of the catalog.

- **OS/VS1 Access Method Services**, GC26-3840, **OS/VS2 Access Method Services**, GC26-3841, and **OS/VS2 Independent Component: Access Method Services**, GC26-3843, which contain a complete description of the commands that are used to copy, print, and load data sets. They also describe the relationships among components, the structure of components, the use of the catalog, and Access Method Services commands that are used to define and delete data sets, list catalog entries, and move data sets from one operating system to another. These publications are directed to the person responsible for establishing and maintaining data sets in an installation.

- **OS/VS1 Virtual Storage Access Method (VSAM) Logic**, SY26-3841, which describes the internal logic of VSAM and of VSAM catalog management.

- **OS/VS2 Catalog Management Logic**, SY26-3826, and **OS/VS2 Independent Component: Catalog Management Logic**, SY26-3847, which describe the internal logic of VSAM catalog management.

Other Required Publications

The reader also needs to be familiar with some of the information presented in the following publications:

- *OS/VS Data Management Services Guide*, GC26-3783, which presents basic concepts such as access method, direct-access storage, and the distinction between data-set organization and data-set processing.
- *OS/VS1 JCL Reference*, GC24-5099, which describes the JCL parameters for VS1 referred to in this publication.
- *OS/VS2 JCL*, GC28-0692, which describes the JCL parameters for VS2 referred to in this publication and describes dynamic allocation.
- *OS/VS2 System Programming Library: TSO*, GC28-0629, which describes dynamic allocation.

Related Publications

The reader may need to be familiar with some of the information presented in the following publications:

Other publications referred to in this publication are:

SUMMARY OF AMENDMENTS

Support for the new functions and data structures listed below has been added to this publication. The changes apply to Release 4 of OS/VS1. Users of Release 3 of OS/VS2 who plan to install the VSAM ICR (independent component release) on their system may use the new information for planning purposes only until the ICR is available. There are no significant changes for Release 3 of OS/VS2.

The changes are:

- Multiple indexes enable subsets of a single data set to be uniquely named, mounted, and processed.

- Control interval size is no longer dependent upon the size of the largest record in a data set. Logical records may span control intervals within a single control area.

- New options allow the sharing of I/O-related control blocks, channel programs, and buffers among several VSAM data sets open at the same time. Definitive descriptions of these options are published in *OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications*.

- Relative record data sets, a new type of data organization, permit the arithmetic calculation of the control interval containing a required record and of the record's position within the control interval.

- GET-previous processing, a variation of sequential retrieval, returns the previous record (relative to current positioning) rather than the next record.

- Improved control-interval processing is an optional performance enhancement that reduces the time and the number of CPU instructions required to gain access to a control interval. This processing is described in *OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications*.

- Enhanced space reclamation makes it possible to reuse a single data set many times as a work file.
INTRODUCTION

VSAM gives you both direct access to records in any order and sequential access to records that follow one another. You can identify a record for retrieval by its key (a unique value in a predefined field in the record), by its displacement from the beginning of the data set, or by its relative record number. These alternative types of access and access options enable you to design a program to suit your requirements for processing data.

With VSAM you can build one or more alternate indexes over a single base data set, so that you need not keep multiple copies of the same information organized in different ways for different applications. In terms of access, an alternate index serves the same purpose as a primary index, but it does not account for space in the base data set and does not require unique keys.

The Access Method Services commands are used to establish and maintain data sets and to copy and print data sets. These commands are described in the appropriate Access Method Services publication.

The macros described in this publication include control block macros and request macros. The macros that are used to build control blocks, described in the chapter "Control Block Macros," are:

- ACB, which is used to build an access-method control block at assembly time.
- EXLST, which is used to build an exit list, which identifies available exit routines; the exit list is built at assembly time.
- RPL, which is used to build a request parameter list at assembly time.
- GENCB, which is used to build an access-method control block, an exit list, or a request parameter list at execution time.

The macros that are used to modify, display, and test the contents of control blocks, also described in the chapter "Control Block Macros," are:

- MODCB, which is used to modify an access-method control block, an exit list, or a request parameter list at execution time.
- SHOWCB, which is used to display fields in an access-method control block, an exit list, or a request parameter list at execution time.
- TESTCB, which is used to test the contents of fields in an access-method control block, an exit list, or a request parameter list at execution time.

The macros used to store, retrieve, and erase records, to position VSAM in a data set, to suspend processing, and to terminate requests, described in the chapter "Request Macros," are:

- GET, which is used to retrieve a record.
- PUT, which is used to store a record.
- ERASE, which is used to delete a record.
- POINT, which is used to position VSAM at a record.
- CHECK, which is used to suspend processing.
- ENDRREQ, which is used to terminate a request.
Types of Data Sets

VSAM has key-sequenced, entry-sequenced, and relative record data sets. The primary difference among the three is the sequence in which data records are loaded into them.

Records are loaded into a key-sequenced data set in key sequence: that is, in the order defined by the collating sequence of the contents of the key field in each of the records. Each record has a unique value, such as employee number or invoice number, in the key field. To determine where to insert a new record into the data set in key sequence, VSAM uses an index that pairs the key of a record with the record's location.

Records are loaded into an entry-sequenced data set without respect to the contents of the records. Their sequence is determined by the order in which they are stored: their entry sequence. Each new record is stored after the last record in the data set.

Records are loaded into a relative record data set in relative record number sequence, or you can supply the relative record number of each record and load them in random order. The data set may be described as a string of fixed-length slots, each of which is identified by a relative record number. When a new record is sequentially inserted, VSAM assigns the record either the next available relative record number in sequence or the number you supplied.

When a data set is created, it is defined as a cluster. A cluster can be a key-sequenced data set, which consists of a data component and an index component, or it can be an entry-sequenced or relative record data set, which consists of only a data component.

Any suballocated VSAM data set that does not have an alternate index and is not associated with key ranges may be used as a work file. That is, you can treat a filled data set as if it were empty and use it again and again, regardless of its old contents.

All VSAM data sets are stored on direct-access storage devices. The records of a data set need not be stored in a continuous area of storage. From your point of view, the area is continuous, starting at address 0. VSAM addresses a point in the area by its displacement, in bytes, from 0, called its RBA (relative byte address). For example, the first record in a data set has RBA 0. The second record has an RBA equal to the length of the first record, and so on. RBAs are independent of a data set's being stored in nonadjacent areas on a volume or on several volumes.

All VSAM data sets must be cataloged in a VSAM catalog. See the appropriate Access Method Services publication for a description of the catalog.

The total space of a data set is considered to be divided into a continuous set of areas called control areas, which are further divided into control intervals. When you retrieve a record, the contents of the control interval in which it is stored are read in by VSAM. A control interval is thus the unit of data transmission between virtual and auxiliary storage.

Key-sequenced and entry-sequenced data records whose lengths exceed control interval size may cross, or span, one or more control interval boundaries within a single control area. Such records are called spanned records. You must specify your intent to use spanned records when you define the data set.
**Key-Sequenced Data Set**

A key-sequenced data set always includes an index, which is a mechanism for keeping track of records. An index relates key values to the relative locations of the records.

The RBAs of records can change in a key-sequenced data set when records are added, deleted, shortened, or lengthened.

A key-sequenced data set permits the full range of options for gaining access to data: keyed access (as well as addressed and control-interval access), insertion, deletion, and changing the length of a record. VSAM keeps track of records in a key-sequenced data set by key field, so that you need refer to a record only by its key field, and not in some location-dependent manner.

**Entry-Sequenced Data Set**

The records in an entry-sequenced data set are in the order they are stored in time. That is, each new record is stored at the end; none is inserted. Records cannot be shortened, lengthened, or moved from one location to another. Records cannot be deleted, although they can be replaced with records of the same length. Once a record is added to an entry-sequenced data set, it stays there and keeps its original RBA. An entry-sequenced data set is essentially a sequential data set, but one whose records can be retrieved at random by direct access and can be updated. The search argument for direct retrieval is a record's RBA.

An entry-sequenced data set is appropriate for applications that require no special ordering of data by the contents of a record. It is appropriate for a log or a journal, because its order corresponds to the chronology of events. To retrieve records randomly from an entry-sequenced data set, you must keep track of the records' RBAs and associate RBAs with the contents of records.

**Relative Record Data Set**

A relative record data set has no index. It is a string of fixed-length slots, each of which is identified by a relative record number from 1 to n, where n is the maximum number of records that can be stored in the data set. Each record occupies a slot and is stored and retrieved by the relative record number of the slot.

Records in a relative record data set are grouped together in control intervals, just as they are in a key-sequenced or an entry-sequenced data set. Each control interval contains the same number of slots. The size of each slot is the record length you specified when you defined the data set.

Relative record data sets can be processed by key or by control interval. With keyed access, a relative record number is treated like a key. You can update records in place, delete records, and insert new records into empty slots. Control-interval processing is described in *OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications*.

You can use a relative record data set in much the same way you would use a BDAM (basic direct-access method) data set in which the data records are not ordered by their contents or their entry sequence.

Figure 1 compares key-sequenced, entry-sequenced, and relative record data sets.
### Alternate Indexes

An alternate index provides a unique way to gain access to a related base data set, so that you need not keep multiple copies of the same information organized in different ways for different applications. For example, a payroll data set indexed by employee number can also be indexed by other fields such as employee name or department number. See the appropriate Access Method Services publication for a complete description of the commands used to define and build an alternate index.

In terms of access, an alternate index performs the same function as the prime index of a key-sequenced data set. The data set over which the alternate index is built is the base cluster. It can be a key-sequenced or an entry-sequenced data set, but not a relative record or a reusable data set.

### Alternate-Index Clusters

The alternate index is an indexed cluster (the alternate-index cluster). It consists of an index component and a data component. The index component is identical in structure, format, and function to the prime index of a key-sequenced cluster. Likewise, the format of the alternate-index data component is identical to the base data set. Therefore, each entry in the sequence set of an alternate-index index component points to a control interval in the alternate-index data component.

When building an alternate index, you can use as the alternate key any field in the base data set's records having a fixed length and a fixed position within each record. The alternate key must be in the first segment of a spanned record. For each alternate key, the data component of the alternate index contains a unique record. This record consists of the alternate key itself, followed by a pointer that is the prime key or RBA of the base data record that contains the alternate key. If more than one base data record contains
the alternate key then the alternate index record contains a pointer to each base data record. These duplicate, or nonunique keys are discussed in the section "Alternate-Index Keys."

Alternate-Index Paths

A path logically relates a base cluster and each of its alternate indexes. It provides a way to gain access to the base data through a specific alternate index. You define a path through Access Method Services. You must name it and you can give it a password, if you choose. The path name subsequently refers to the base cluster/alternate-index pair. This means that when you refer to a path (by way of the OPEN macro, for example), both the base cluster and the alternate index are affected (opened).

Alternate-Index Records

Each record in the data component of an alternate-index cluster is variable-length and contains system header information, the alternate key, and at least one pointer to a base data record. Data component records may span control intervals.

System Header Information

System header information is fixed length and indicates:

- Whether the alternate index record contains (1) prime keys or RBA pointers and (2) unique or nonunique keys
- The length of each pointer
- The length of the alternate key

Alternate-Index Keys

Unless the base data records span control intervals, any field in the base data records that has a fixed length and a fixed position within the record can be an alternate key. The alternate key must be in the first control interval of a spanned record. When an alternate index is created, the alternate keys are extracted from the base data records and ordered in collating sequence. If you build several alternate indexes over a base cluster, the alternate key fields of the different alternate indexes may overlap each other in the base data records. They can also overlap the prime key.

Keys in the index component of an alternate index or of a key-sequenced base cluster are compressed. Keys in the data component of an alternate index are not compressed. That is, the entire key is represented in the alternate-index record.

An alternate key may refer to more than one record in the base cluster. For example, if an alternate index is established by department number over a payroll data set organized by employee number, there will be several employees with the same department number. In other words, there will be several prime-key pointers (employee numbers) in the alternate-index record, one for each occurrence of the alternate key (department number) in the base data set. When multiple pointers are associated with a given alternate key value, the alternate key is said to be nonunique; if only one pointer is associated with the alternate key, it is unique.
Alternate-Index Pointers

An alternate index uses prime keys if the base cluster is a key-sequenced data set and RBAs if the base cluster is an entry-sequenced data set.

For a nonunique key, multiple pointers are associated with it. The pointers are ordered by their arrival times. That is, if a base data record is updated with a key change, or if a new record is inserted with the same alternate key value the new prime-key pointer is added to the end of the alternate-index record. In the case of a key change, the old pointer is deleted.

A prime-key pointer has the same length as the prime key field of the base data record it points to. The maximum number of pointers that can be associated with a given alternate key is 32767, provided the maximum record length for spanned records is not exceeded.

Alternate-Index Maintenance

VSAM assumes alternate indexes are synchronized with the base cluster at all times and makes no synchronization checks during open processing; therefore, all structural changes made to a base cluster must be reflected in its alternate index or indexes. This maintenance is called index upgrade. You can maintain your alternate indexes or you can have VSAM maintain them. When the data set is defined with the UPGRADE attribute, VSAM will update the alternate index immediately when there is a change to the associated base data cluster. VSAM opens all the UPGRADE alternate indexes for a base cluster whenever the base cluster is opened for output and updates them if necessary.

All the alternate indexes of a given base cluster that have the UPGRADE attribute belong to the upgrade set. The upgrade set is updated whenever a base data record is inserted, erased, or updated. The upgrading is part of a request and VSAM completes it before returning control to your program. If the upgrade fails because of a logical error, any modifications made to the base data or to another alternate index are nullified, and the request that caused the upgrade is rejected.

If you specify NOUPGRADE when the data set is defined, you must provide a way to reflect insertions, deletions, and changes made to the base cluster in all associated alternate indexes.
Processing Options

Processing options include:

- Types of access (keyed or addressed, and sequential, skip sequential, or direct)
- Exit routines for special processing

You can gain access to a data set with a mixture of options. For instance, if you were processing two portions of a data set concurrently, you might process one portion directly, asynchronously, using a work area; you might process the other sequentially, synchronously, in the I/O buffer. You could also alternate among the options to process a data set, switching, say, from direct to sequential access when you got to a point where you wanted to process records in ascending sequence.

Processing options are specified in macros that generate control blocks when your program is assembled (ACB, EXLST, and RPL macros) or executed (GENCB macro). Each request for some action is associated with a request parameter list, which, in association with other control blocks, supplies the processing options for the request. See the chapter “Control Block Macros” for a description of the macro instructions and of the specification of the processing options.

When you issue a request for a record, you can either wait until the request is completed to continue processing or go on with processing that is not dependent upon the first request while it is being carried out. Overlapping processing in this way can improve the performance of your job.

VSAM can keep track concurrently of positions in a data set for many requests to a data set. You can thus process many portions of a data set during the same period of time. Such concurrent access may be used to increase throughput, where each request can be processed independently of the others.

The standard request for access retrieves, stores, or deletes a single record. The standard request is described by a parameter list that indicates a single record. By chaining parameter lists together, you can retrieve or store many records with one request. You may not use chained parameter lists to update or delete records; you may use chained parameter lists only to retrieve records or to store new records.

Types of Access

VSAM allows both sequential and direct access for each of its three types of data sets. Sequential access of a record depends on the position, with respect to the key, the relative byte address of the previously processed record, or the relative record number; direct access does not. During sequential access, records retrieved by key are in key sequence, records retrieved by RBA are in entry sequence, and records retrieved by relative record number are in relative record number sequence. To retrieve records after initial positioning, you don’t need to specify a key, an RBA, or a relative record number. VSAM automatically retrieves or stores the next record in order, either next in key sequence, next in entry sequence, or next in relative record number sequence, depending on whether you’re processing by key, by RBA, or by relative record number.

With direct access, the retrieval or storage of a record is not dependent on the key, the RBA, or the relative record number of any previously retrieved
record. You must fully identify the record to be retrieved or stored by key, by
RBA, or by relative record number.

**GET-previous** processing is a variation of normal keyed or addressed
sequential processing. Instead of retrieving or updating the next record in
ascending sequence (relative to current positioning in the data set),
GET-previous processing returns or updates the next record in descending
sequence. You can select GET-previous processing for POINT, GET, PUT
(update only), and ERASE operations. GET-previous processing is not
permitted with control-interval or skip-sequential processing.

VSAM allows a processing program or its subtasks to process a data set with
multiple concurrent sequential and/or direct requests, each requiring that
VSAM keep track of a position in the data set, with a single opening of the
data set. Access can be to the same part or to different parts of a data set.

You can use a suballocated VSAM data set as a work file, if the data set does
not have an alternate index and is not associated with key ranges. That is, you
can treat a filled data set as if it were empty and use it again and again
regardless of its old contents. To reuse a data set, you need only to define it
as reusable and specify that it be reset when you open it.

For a key-sequenced data set the primary form of access is keyed access,
using an index. For an entry-sequenced data set without an alternate index,
the only forms of access are addressed (using the RBA determined for a
record when it was stored in the data set) and control-interval access. For a
relative record data set, the only forms of access are keyed (using the relative
record number as the key) and control-interval access. Control-interval access
is described in *OS/VS Virtual Storage Access Method (VSAM) Options
for Advanced Applications*.

If you use addressed access to process key-sequenced data, you should
consider the possibility that RBAs may have changed during previous keyed
access.

For examples of keyed and addressed retrieval, storage, deletion, and update,
see the chapter "Request Macros" later in this publication.

---

**Retrieve by Key**

Keyed sequential access for a key-sequenced data set depends on where the
previous macro request positioned VSAM with respect to the key sequence
defined by the index. When your program opens the data set for keyed access,
VSAM is positioned at the first record in the data set in key sequence to begin
keyed sequential processing. The POINT macro instruction positions VSAM
at the record whose key you specify. If the key is a leading portion of the key
field, a *generic key*, the record positioned to is the first of the records having
the same generic key. A subsequent GET macro retrieves the record VSAM is
positioned at. The GET then positions VSAM at the next record in key
sequence. VSAM checks positioning when processing modes are changed
between requests. The POINT macro can position either forward or backward
in the data set, depending on whether FWD or BWD was specified for the
OPTCD operand.

When you are processing by way of a path, records from the base cluster are
returned according to ascending or, if you are retrieving the previous record,
descending alternate key values. If there are several records with a nonunique
alternate key, the records are returned in the order in which they were
entered into the alternate index. VSAM sets a return code in the RPL when
there is at least one more record with the same alternate key. For example, if
there are three data records with the alternate key 1234, the return code
would be set during the retrieval or records one and two and would be reset
during retrieval of the third record.

Keyed sequential retrieval for a relative record data set causes the records to
be returned in ascending or, if you are retrieving the previous record,
descending numerical order, based on the current positioning for the data set.
Positioning is established in the same way as for a key-sequenced data set,
and the relative record number is treated as a full key. If a deleted record is
encountered during sequential retrieval, it is skipped over and the next record
is retrieved. The relative record number of the retrieved record is returned in
the ARG field of the RPL.

Keyed direct retrieval for a key-sequenced data set does not depend on prior
positioning; VSAM searches the index from the highest level down to the
sequence set to retrieve a record. You can specify the record to be retrieved
by supplying one of the following:

• The exact key of the record
• An approximate key, less than or equal to the key field of the record
• A generic key

You can use approximate specification when you do not know the exact key.
If a record actually has the key specified, VSAM retrieves it; otherwise, it
retrieves the record with the next higher key. Generic key specification for
direct processing causes VSAM to retrieve the first record having that generic
key. If you want to retrieve all the records with the generic key, specify NSP
in your direct request. That causes VSAM to position itself at the next record
in key sequence. You can then retrieve the remaining records sequentially.

When you use direct or skip-sequential access to process a path, a record
from the base data set is returned according to the alternate key you have
specified in the ARG operand of the RPL macro. If the alternate key is not
unique, the record which was first entered with that alternate key is returned
and a return code (duplicate key) is set in the RPL. To retrieve the remaining
records with the same alternate key, specify the NSP option when retrieving
the first record and then switch to sequential processing.

To use direct or skip-sequential access to process a relative record data set,
you must supply the relative record number of the record you want in the
ARG operand of the RPL macro. If you request a deleted record, the request
will cause a no-record-found logical error.

When you indicate the key of the next record to be retrieved during
skip-sequential retrieval, VSAM skips to its index entry by using horizontal
pointers in the sequence set to get to the appropriate sequence-set index
record to scan its entries. The key of the next record must always be higher in
sequence than the key of the preceding record.

A relative record data set has no index; VSAM takes the number of the
record to be retrieved and calculates the control interval that contains it and
its position within the control interval.
Delete by Key

An ERASE macro instruction that follows a GET for update deletes the record that the GET retrieved. A record is physically erased in the data set when you delete it. The space the record occupied is then available as free space.

You can erase a record from the base cluster of a path only if the base cluster is a key-sequenced data set. If the alternate index is in the upgrade set (that is, UPGRADE was specified when the alternate index was defined), it is modified automatically when you erase a record. If the alternate key of the erased record is unique, the alternate index data record with that alternate key is also deleted.

You can erase a record from a relative record data set after you have retrieved the record for update. The record is set to binary zeros and the control information for the record is updated to indicate an empty slot. You can reuse the slot by inserting another record of the same length into it.

Store by Key

To store records in ascending key sequence throughout a data set, you can use sequential, skip-sequential, or direct access. For sequential or skip-sequential processing, VSAM scans the sequence set of the index; for direct processing, VSAM searches the index from top to bottom.

A PUT macro instruction stores a record. A PUT for update following a GET for update stores the record that the GET retrieved. To update a record, you must previously have retrieved it for update.

When VSAM detects that two or more records are to be inserted in sequence into a collating position (between two records) in a data set. VSAM uses a technique called mass sequential insertion to buffer the records being inserted, thereby reducing I/O operations. Using sequential instead of direct access in this case enables you to take advantage of this technique. You can also extend your data set (resume loading) by using sequential insertion to add records beyond the highest key or relative record number.

Sequential insertion in a relative record data set causes a record to be assigned the next available number in sequence, which is the next available relative record number greater than the position established by a previous record. The assigned number is returned in the ARG field of the RPL.

Direct or skip-sequential insertion of a record into a relative record data set causes the record to be placed as specified by the relative record number in the ARG field of the RPL. You must insert the record into a slot that does not contain a record.

You can insert and update data records in the base cluster by way of a path, provided the PUT request does not result in nonunique alternate keys in an alternate index which you have defined with the UNIQUE parameter. If the alternate index is in the upgrade set (that is, you specified UPGRADE when you defined the alternate index), the alternate index is modified automatically when you insert or update a data record in the base cluster. If the updating of the alternate index results in an alternate-index record with no pointers to the base cluster, the alternate-index record is erased.
Retrieve by Address

Positioning for addressed sequential retrieval is done by RBA rather than by key. When a processing program opens a data set for addressed access, VSAM is positioned at the first record in the data set in entry sequence to begin addressed sequential processing. A POINT positions VSAM for sequential access beginning at the record whose RBA you have indicated. A sequential GET causes VSAM to retrieve the data record at which it is positioned and positions VSAM at the next record in forward or backward direction.

With direct processing, you can optionally specify that the position be maintained following the GET. Your program can then process the subsequent records sequentially in either a forward or backward direction.

Addressed sequential access retrieves records in forward or backward direction. If addressed sequential retrieval is used for a key-sequenced data set, records will not be in their key sequence if there have been control interval or control area splits.

Addressed direct retrieval requires that the RBA of each individual record be specified, since previous positioning is not applicable. The address specified for a GET or a POINT must correspond to the beginning of a data record; otherwise, the request is invalid.

Delete by Address

The ERASE macro can be used only with a key-sequenced data set to delete a record that you have previously retrieved for update.

With an entry-sequenced data set, you are responsible for marking a record you consider to be deleted. As far as VSAM is concerned, the record is not deleted. You can reuse the space occupied by a record marked as deleted by retrieving the record for update and storing in its place a new record of the same length.

Store by Address

VSAM does not insert new records into an entry-sequenced data set, but adds them at the end. With addressed access of a key-sequenced data set, VSAM does not insert or add new records.

A PUT macro instruction stores a record. A PUT for update following a GET for update stores the record that the GET retrieved. To update a record, you must previously have retrieved it for update. You can update the contents of a record with addressed access, but you cannot alter the record’s length. Neither can you alter the prime key field of a record in a key-sequenced data set.

To change the length of a record in an entry-sequenced data set, you must store it either at the end of the data set (as a new record) or in the place of an inactive record of the same length. You are responsible for marking the old version of the record as inactive.
Exit Routines for Special Processing

An exit is a branch that VSAM takes to an optional user-supplied routine when certain unusual conditions occur or when certain recurrent but unpredictable events happen. Exits are defined for:

- Logical error (LERAD), which is used when the processing program makes an invalid request for access to data.
- Physical error (SYNAD), which is used to handle physical-error conditions.
- Exception handling (EXCEPTIONEXIT), which monitors physical-error conditions on a data set basis. This exit is specified via the Access Method Services DEFINE command and it is taken before a SYNAD exit if both are specified.
- End of data set (EODAD), which is used when the processing program has attempted to point to or retrieve sequentially a record beyond the last record in the data set.
- Journalizing a transaction or keeping track of RBA change (JRNAD), which is used to keep track of any change to the RBAs of records.
- User-security-verification (USVR), which is used to make security checks in addition to verification of passwords.

The routine to which VSAM exits may be a subroutine in the processing program or a separate load module. An exit routine is identified as available for use in an exit list associated with one or more access-method control blocks. See the chapter “Control Block Macros” for information on how the exit list is created, modified, tested, and displayed. See the chapter “User-Written Exit Routines” for detailed information about the exit routines. For information about exception exits, see the appropriate Access Method Services publication.

Utility Functions Carried Out by Access Method Services

Access Method Services is a multifunction service program that is used to define a VSAM data set and load records into it, convert a sequential or an indexed-sequential data set to the VSAM format, list VSAM catalog information or data-set records, copy a data set for reorganization, create a backup copy of a data set, recover from certain types of damage to a data set, and make a data set portable from one operating system to another.
Processing a VSAM Data Set with an ISAM Program

VSAM provides an interface program that permits you to use programs coded to use ISAM (indexed-sequential access method) to process VSAM data sets. To use the ISAM interface, you must convert indexed-sequential data sets to VSAM data sets, convert ISAM JCL to VSAM JCL, and ensure that your existing ISAM programs meet the restrictions for using the interface.

To convert an indexed-sequential data set to a VSAM data set that you can process either with an ISAM program by way of the ISAM interface or with a VSAM program, you use Access Method Services to define a key-sequenced data set in a VSAM catalog and allocate space for it. You may use an ISAM program by way of the ISAM interface to load records into the data set, or you may use Access Method Services REPRO command. For more details about the procedure, see the chapter “Using ISAM Programming with VSAM.”

Using the Time Sharing Option (TSO) with VSAM

TSO is a subsystem of OS/VS2 that provides conversational time sharing from remote terminals. You can use TSO with VSAM to:

- Execute Access Method Services commands directly as TSO commands.
- Execute a program to process a VSAM data set.
- Execute a program to call Access Method Services.
- Dynamically allocate a VSAM data set and use VSAM macros to process the data set.
- Allocate a VSAM data set by way of a LOGON procedure and use either VSAM or ISAM macros to process the data set.

For details about writing and executing programs and allocating data sets with TSO, see OS/VS2 TSO Terminal User's Guide, and OS/VS2 TSO Command Language Reference. For information about dynamic allocation, see OS/VS2 JCL.
OPENING AND CLOSING A DATA SET

This chapter describes (1) the job control language, required in VS1 and optional in VS2, used to connect a data set and the program that is to use it, how to code the VSAM AMP parameter, and how to identify user catalogs for jobs or job steps; (2) the OPEN macro; and (3) the CLOSE macro.

A necessary link between a processing program and the data set to be processed is the data-set name. When JCL is used, the access-method control block gives the name of the DD statement so that the OPEN macro can make the connection between the program and the data set named in the DD statement, and thus connect program and data. When JCL is not used, the data set can be dynamically allocated. See OS/VS2 JCL and OS/VS2 System Programming Library: TSO for an explanation of dynamic allocation.

How to Code JCL

All VSAM data sets are cataloged in a VSAM catalog. To identify a VSAM data set through JCL, it is sufficient to specify a DD statement of the form:

```
//ddname DD DSNAME=dsname,DISP={OLD | SHR}
```

The DSNAME parameter specifies the name of the data set you are processing. Each VSAM data set is defined as a component of a cluster: a key-sequenced data set is made up of a data component and an index component; and an entry-sequenced and a relative record data set are made up of only a data component. If you need to process a component separately, you may specify the component's name in the DSNAME parameter.

If a data set in a job step is defined in a user catalog, it is also necessary to identify the user catalog either by means of a JOBCAT or a STEPCAT DD statement or by means of dynamic allocation.

Because the operating system does not disallow OS/VS DD parameters and subparameters that don't apply to a VSAM data set, you should be aware of the DD parameters and subparameters that have clear and unambiguous meaning when used with VSAM. Figure 2 shows the DD parameters and subparameters that can be used with VSAM and indicates their meaning for a VSAM data set. DD parameters and subparameters not shown in Figure 2 should be avoided. For an explanation of potential problems you may encounter with those parameters and subparameters, see the appropriate Access Method Services publication.

Coding a DD Statement for a User Catalog

The master catalog is assumed to contain the definition of the data set described in a DD statement if no user catalog is indicated or if the definition is not found in the user catalog(s) that are indicated. A user catalog is specified either for all of the steps of a job or for a particular step. To specify a job user catalog, place a DD statement with the ddname JOBCAT before the first EXEC statement after the JOB statement and after a JOBLIB statement, if any:

```
//EXAMPLE JOB ...
//JOBLIB DD DSNAME=USER.LIB,DISP=SHR
//JOBCAT DD DSNAME=usercatalogname,DISP=SHR
// EXEC ...
```

<td>Works as in OS/VS.</td>
</tr>
<tr>
<td>SER</td>
<td></td>
<td>The volume serial number(s) used in the Access Method Services DEFINE command for the data set must match the volume serial numbers in the VOLUME=SER specification when the data set is defined. After a VSAM data set is defined, the volume serial number(s) need not be specified on a DD statement to retrieve or process the data set. If, however, VOLUME=SER and UNIT=type are specified, only those volumes specifically named are initially mounted. Other volumes may be mounted when they're needed if at least one of the units allocated to the data set is not shareable and the number of OPENs issued against the volume is less than or equal to 1, or the unit count is greater than the total number of volumes initially mounted. One unit is made unshareable when unit count is less than the number of volume serial numbers specified or when DEFER is specified.</td>
</tr>
</tbody>
</table>

Figure 2. JCL DD Parameters
To specify a job-step user catalog, place a DD statement with the ddname STEPCAT after the EXEC statement of the step:

```
// EXEC ...
//STEPCAT DD DSNAME=userdatacatalogname,DISP=SHR
```

The order in which catalogs are searched when an existing entry is to be located is:

- If a catalog is specified in a CATALOG parameter, only that catalog is searched. In VS1, if a catalog is specified in the CATALOG parameter and it is not also a master, STEPCAT, or JOBCAT catalog, the dname parameter must also be specified in CATALOG.

- Any user catalog(s) specified in the current job step (STEPCAT) or, if none is specified for the job step, any user catalog(s) specified for the current job (JOBCAT). If more than one catalog is specified for the job step or job, the job-step or job catalogs are searched in order of concatenation.

- For VS1, if the entry is not found, the master catalog.

- For VS1, if the entry is not found, the system catalog.

- For VS2, if the entry is not found and the entry's name is a qualified name and the first qualifier (that is, the first one to eight characters before any period) is the same as the name or alias of a user catalog or the alias of a control volume, that user catalog or control volume is searched; otherwise, the master catalog.

**Restriction:** Control volumes are not searched when (1) an existing data set is to be deleted except when the data set to be deleted is a non-VSAM data set, or (2) when an existing data set is to be altered.

**Coding the AMP Parameter**

VSAM uses one additional JCL parameter: AMP. It has subparameters for:

- Overriding operands specified by way of the ACB, EXLST, and GENCB macros
- Supplying operands missing from the ACB or GENCB macro
- Indicating checkpoint/restart options
- Indicating options when using ISAM macros to process a key-sequenced data set
- Indicating that the data set is a VSAM data set when you specify unit and volume information or DUMMY in the DD statement
- Indicating that you want VSAM to supply storage dumps of the access-method control block(s) that identify this DD statement

The AMP parameter takes effect when the data set defined by the DD statement is opened.
The format of the AMP parameter is:

```
//... DD ...[AMP=['AMORG']
[,'BUFND = number']
[,'BUFNI = number']
[,'BUFSP = number']
[,'CROPS = [RCK | NCK | NRE | NRC]']
[,'OPTCD = [I | L | IL]']
[,'RECFM = [F | FB | V | VB]']
[,'STRNO = number']
[,'SYNAD = modulename']
[,'TRACE']]
```

where:

**AMORG**

specifies that the DD statement defines a VSAM data set. You need to (and must) specify AMORG only when you include unit and volume information or DUMMY in the DD statement. When you specify unit and volume information or DUMMY, the system doesn’t have to search a catalog to find out what volume(s) are required, and therefore doesn’t know that the DD statement defines a VSAM data set. You never have to specify unit and volume information unless you want to have a subset of the volumes on which the data set is stored mounted or want to cause mounting to be deferred.

**BUFND = number**
**BUFNI = number**
**BUFSP = number**

specifies that one or more of these values is to override whatever was specified in the ACB or GENCB macro, or that one or more of these values is to be provided if not previously specified.

**CROPS = [RCK | NCK | NRE | NRC]**

specifies one of four checkpoint/restart options, which are described in detail in *OS/VS Checkpoint/Restart*. If you specify an option that is not applicable for a data set, such as the data-erase test for an input data set, the option is ignored.

**RCK**

specifies that a data-erase test and data-set-post-checkpoint modification tests are to be performed.

**NCK**

specifies that data-set-post-checkpoint modification tests are not to be performed.

**NRE**

specifies that a data-erase test is not to be performed.

**NRC**

specifies that neither a data-erase test nor data-set-post-checkpoint modification tests are to be performed.

**OPTCD = [I | L | IL]**

specifies the processing of records flagged for deletion (binary 1s in the first byte) with an ISAM processing program using the ISAM interface. I and L are described in the chapter “Using ISAM Programming with VSAM.”

RECFM={F | FB | V | VB}
specifies record format in the same way as the DCB (data control block) parameter that is used for processing an indexed-sequential data set. You use it when processing a VSAM data set with an ISAM processing program to indicate what record format the processing program assumes. The options are described in the chapter “Using ISAM Programming with VSAM.”

STRNO=number
specifies a value that is to override the STRNO value specified in the ACB or GENCB macro, or to provide a value if one was not specified.

SYNAD=modulename
specifies a value that is to override the address of a SYNAD exit routine specified in the EXLST or GENCB macro that generates the exit list. The exit list intended is the one whose address is specified in the access-method control block that links this DD statement to the processing program. If no SYNAD exit was specified, the SYNAD parameter of AMP is ineffective. You can also use this parameter, when you are processing a VSAM data set with an ISAM processing program, to provide an ISAM SYNAD routine or to replace one with another.

TRACE
specifies that Generalized Trace Facility (GTF) is to be active, along with your processing job, to gather information associated with opening and closing data sets and end-of-volume processing. You can print the trace output with the IMDPRDMP service program.

Note: See “AMP Parameter Specification” in the chapter “Using ISAM Programming with VSAM” for additional information on the use of the AMP parameter with an ISAM processing program.

Subparameters must be enclosed in apostrophes. Apostrophes can enclose each individual subparameter or group of subparameters. If you have more than one pair of apostrophes, you must enclose all of the subparameters in a pair of parentheses. For example, AMP=‘AMORG,TRACE’ or AMP=('AMORG','TRACE'). If the subparameters continue from one line to another, a pair of apostrophes cannot extend from one line to the next, and you must therefore use a pair of parentheses to enclose all of the subparameters.

The AMP parameter cannot be defined as a symbolic parameter (a symbol preceded by an ampersand that stands for a parameter or the value assigned to a parameter or subparameter in a cataloged or in-stream procedure).

OPEN Macro (Connect Program and Data)
Before your program can issue requests for access to a data set, it must open the data set for processing. Opening a data set causes VSAM to have the volume(s) on which it is stored mounted if necessary and to verify that the data set matches the description implied by the ACB or GENCB macro (for example, MACRF=KEY implies that the data set is a key-sequenced data set).

OPEN causes VSAM to construct control blocks (other than those you caused to be built by the ACB, EXLST, and GENCB macros) that it needs to process your requests for access to the data set. It determines what processing options are to be used by merging the information in the DD statement and
the catalog definition of the data set with the information in the
access-method control block and the exit list. The order of precedence is:

1. The DD-statement AMP parameters
2. The ACB, EXLST, or GENCB operands
3. The catalog entry for the data set

For example, if information about buffer space is specified both in the DD
statement and in the ACB or GENCB macro, the values in the DD statement
override those in the macro. Catalog information acts as a default when
buffer space specified in the DD statement or in the macro is less than the
minimum specified when the data set was defined or when buffer space is
specified in neither the DD statement nor the macro.

VSAM also checks the password that your program specified against the
appropriate password (if any) in the catalog definition of the data set. The
password required depends on the kind of access specified in the
access-method control block (for example, is access for retrieval or for
update), as follows:

- Full access allows you to perform all operations (retrieving, updating,
inserting, and deleting) on a data set and any index or catalog record
associated with it. The master password allows you to delete or alter the
catalog entry for the data set or catalog it protects.
- Control-interval access requires the control password. The control
password allows you to use control-interval access and to retrieve, update,
insert, or delete records in the data set it protects. See OS/VS Virtual
Storage Access Method (VSAM) Options for Advanced Applications, for
information on the use of control-interval access.
- Update access requires the update password. The update password allows
you to retrieve, update, insert, or delete records in the data set it protects.
- Read access requires the read password. The read password allows you to
examine records in the data set it protects; the read password does not
allow you to add, change, or delete records.

A password of one level authorizes you to do everything that a password of a
lower level authorizes you to do. Password protection is further described in
the appropriate Access Method Services publication.

The format of the OPEN macro is:

```
[ label ] OPEN ( address [ , ( options ) ] , ... )
```

where:

- `label`
  is one to eight characters that provides a symbolic address for the OPEN
  macro.

- `address`
  specifies the address of the access-method control block or DCB for the
data set(s) to be opened. You may specify the address in register notation
(using a register from 2 through 12—in parentheses) or specify it with an
expression that generates a valid relocatable A-type address constant. If
you use register notation to open only one data set, you must enclose
the expression identifying the register in two sets of parentheses: for example,
OPEN ((2)).
Options

Options are options parameters for use only in opening non-VSAM data sets. If any options are specified with the address of an access-method control block, VSAM ignores them.

Because the OPEN operands are positional, include a comma for options (even if you don't specify options) before a subsequent operand.

Return Codes from OPEN

When your program receives control after it has issued an OPEN macro, register 15 indicates whether all of the VSAM data sets were opened successfully:

<table>
<thead>
<tr>
<th>Reg. 15</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>All data sets were opened successfully.</td>
</tr>
<tr>
<td>4</td>
<td>All data sets were opened successfully, but one or more warning messages were issued (codes less than X'80').</td>
</tr>
<tr>
<td>8</td>
<td>At least one data set (VSAM or non-VSAM) was not opened successfully; the access-method control block was restored to the contents it had before OPEN was issued, or, if the data set was already open, the access-method control block remains open and is not changed.</td>
</tr>
<tr>
<td>12</td>
<td>A non-VSAM data set was not opened successfully when a non-VSAM and a VSAM data set were being opened at the same time; the non-VSAM data control block was not restored to the contents it had before OPEN was issued (and the data set cannot be opened without the control block's being restored).</td>
</tr>
</tbody>
</table>

If register 15 contains 4, 8, or 12, you can find out whether a VSAM data set had a warning message, or wasn't opened successfully and why, by issuing SHOWCB to display the ERROR field in each access-method control block specified in OPEN. (See “SHOWCB Macro (Display an Access-Method Control Block)” in the chapter “Control Block Macros.”) Figure 3 shows the possible return codes that you may get from OPEN in the ERROR field in the access-method control block. In addition to these return codes, VSAM writes a message to the operator console and the programmer's listing to further explain the error. See OS/VS Message Library: VSl System Messages and OS/VS Message Library: VS2 System Messages for a listing of VSAM messages for VSl and VS2, respectively.

Example: OPEN Macro

In this example, an OPEN macro is used to open two data sets. The access-method control block for one data set was generated at execution; the other was generated at assembly.

<table>

1 Options and restrictions are described in OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications.

Figure 3 (Part 2 of 2). OPEN Return Codes in the ERROR Field of the Access-Method Control Block

CLOSE Macro (Disconnect Program and Data)

Disconnecting your program from a data set causes VSAM to write out any buffers of data or index whose contents have changed and which haven't already been written out. It causes VSAM to put back into the catalog the updated information that was brought into virtual storage when the data set was opened, and to write records in the SMF data set if you are using SMF. VSAM also releases virtual-storage space and restores your access-method control block(s) to the contents they had when the OPEN macro was issued. To process the data set again, you must reopen it.

The format of the CLOSE macro is:

```
[ label ]  CLOSE  ( address [,options ]...)
[ ,TYPE=T ]
```

where:

**label**

is one to eight characters that provides a symbolic address for the CLOSE macro.

**address**

specifies the address of the access-method control block or DCB for each data set to be closed. You may specify the address in register notation (using a register from 2 through 12—in parentheses) or specify it with an expression that generates a valid relocatable A-type address constant. If you specify only one address with a register, you must enclose the expression identifying the register in two sets of parentheses: for example, CLOSE ((2)).
options

are options parameters for use only in closing non-VSAM data sets. If any options are specified with the address of an access-method control block, VSAM ignores them. Because the CLOSE operands are positional, include a comma for options (even if you don’t specify options) before a subsequent operand.

TYPE=T

specifies that VSAM is to complete outstanding I/O operations and update the catalog, but not disconnect the program from the data.

You can issue a temporary CLOSE macro to cause VSAM to complete outstanding I/O operations, put back into the catalog the updated information that was brought into virtual storage when the data set was opened, and write records in the SMF data set if you are using SMF. A temporary CLOSE doesn’t disconnect the program from the data set, so your program can continue to process the data set without issuing an OPEN macro again.

You must close and reopen a newly loaded VSAM data set before you can issue GETs and PUTs. A temporary close is not adequate for this purpose.

Note: If you are subtask-sharing or if you have issued an asynchronous request for access to a data set, you must issue a CHECK or an ENDREQ on all RPLs before you issue a temporary CLOSE. Concurrent data set I/O activity will cause unpredictable results during a temporary close.

Return Codes from CLSO E

When your program receives control after it has issued a CLOSE macro, register 15 indicates whether all of the VSAM data sets were closed successfully:

Reg. 15 Condition
0 All data sets were closed successfully.
4 At least one data set (VSAM or non-VSAM) was not closed successfully.

If register 15 contains 4, you can use SHOWCB to display the ERROR field in each access-method control block to find out whether a VSAM data set wasn’t closed successfully and why. (See “SHOWCB Macro (Display an Access-Method Control Block)” in the chapter “Control Block Macros.”) Figure 4 gives the return codes that the ERROR field may contain following CLOSE. In addition to these return codes, VSAM writes a message to the operator’s console and the programmer’s listing to further explain the error. See OS/VS Message Library: VS1 System Messages and OS/VS Message Library: VS2 System Messages, for a listing of messages for VS1 and VS2, respectively.

Figure 4. CLOSE Return Codes
CONTROL BLOCK MACROS

The control block macros are used to build control blocks and to modify, display, and test their contents. Some of these macros work at assembly time; others work at execution time. The macros are:

- **ACB**, which is used to generate an access-method control block at assembly time. An access-method control block must exist before a data set can be opened.

- **EXLST**, which is used to generate an exit list at assembly time. An exit list is a list of user-written routines that can be associated with one or more access-method control blocks. Except for an exception exit, which is specified via Access Method Services, a user-written routine must be identified in an exit list to be available to handle unusual conditions.

- **RPL**, which is used to generate a request parameter list at assembly time. A request parameter list is required for use with the request macros to define the characteristics of the request.

- **GENCB**, which is used to generate an access-method control block, an exit list, or a request parameter list at execution time. An access-method control block must exist before a data set can be opened. An exit list identifies any user-written routines provided. A request parameter list is required to define (specify processing) an action for a request macro.

- **MODCB**, which is used to modify or make an addition to an access-method control block, an exit list, or a request parameter list at execution time.

- **SHOWCB**, which is used to display fields in an access-method control block, an exit list, or a request parameter list at execution time.

- **TESTCB**, which is used to test the contents of fields in an access-method control block, an exit list, or a request parameter list at execution time.

Generating a control block at assembly time (ACB, EXLST, and RPL macros) has the advantage of generating the control block only once. When a control block is generated at assembly time, you are, however, exposed to the possibility of having to reassemble your program if you adopt a new version of VSAM in which the format of a control block has changed. Generating a control block at execution time (GENCB macro) has the advantage of not requiring reassembly of a program if the format of a control block changes in a subsequent version of VSAM. It has the disadvantage of having to execute the macro each time the program is executed.

**Specifying Options at Assembly or Execution**

For specifying processing options, you can use macros that generate control blocks when your program is assembled (ACB, EXLST, and RPL macros) or use a macro that generates control blocks when the program is executed (GENCB macro).

The macros that work at assembly time allow you to specify values for operands as absolute numeric expressions, as character strings, as codes, as
expressions that generate valid relocatable A-type address constants. The macros that work at execution allow you to specify them in those ways and also in:

- Register notation, where the expression designating a register from 2 through 12 is enclosed in parentheses; for example, (2) and (REG), where REG is a label equated to a number from 2 through 12
- An expression of the form (S,scon), where scon is an expression valid for an S-type address constant, including the base-displacement form
- An expression of the form (*,scon), where scon is an expression valid for an S-type address constant, including the base-displacement form, and the address specified by scon is indirect—that is, it gives the location of the area that contains the value for the operand

For most programming applications, you can conveniently use register notation or absolute numeric expressions for numbers, character strings for names, and register notation or expressions that generate valid A-type address constants for addresses. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution time.

You can write a reentrant program only with execution-time macros. “Appendix B: List, Execute, and Generate Forms of GENCB, MODCB, SHOWCB, and TESTCB” describes alternate ways of coding these macros for reentrant programs. The standard form of these macros is described in this chapter.

Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros

The GENCB, MODCB, SHOWCB, and TESTCB macros are executable (unlike the ACB, EXLST, and RPL macros): they cause control to be given to VSAM to perform the indicated task. VSAM indicates the task was completed by a code in register 15:

<table>
<thead>
<tr>
<th>Reg. 15</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Task completed.</td>
</tr>
<tr>
<td>4</td>
<td>Task not completed.</td>
</tr>
<tr>
<td>8</td>
<td>An attempt was made to use the execute form of a macro (see “Appendix B: List, Execute, and Generate Forms of GENCB, MODCB, SHOWCB, and TESTCB”) to modify a keyword that isn’t in the parameter list.</td>
</tr>
</tbody>
</table>

When register 15 contains 4, register 0 contains a code indicating the reason VSAM couldn’t perform the task. Figure 5 describes each error code that can be returned in register 0.

These macros build a parameter list that describes in codes the actions indicated by the operands you specify. The parameter list is passed to VSAM to take the indicated actions. An error can occur because you specified the operands incorrectly or, if you constructed the parameter list yourself, because the parameter list was encoded incorrectly. If you construct the list yourself you can also get in register 0 reason codes 1, 2, 3, 10, 14, and 18. See OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications for an explanation of these reason codes and for an explanation of how to construct parameter lists for GENCB, MODCB, SHOWCB, and TESTCB.
Return Code | Applicable Macros* | Reason VSAM Couldn't Perform the Task
---|---|---
1 | G,M,S,T | The request type (generate, modify, show, or test) is invalid.
2 | G,M,S,T | The block type (access-method control block, exit list, or request parameter list) is invalid.
3 | G,M,S,T | One of the keyword codes in the parameter list is invalid.
4 | M,S,T | The block at the address indicated is not of the type you indicated (access-method control block, exit list, or request parameter list).
5 | S,T | Access-method control block fields were to be shown or tested, but information is available only when the data set is an open VSAM data set, and either it isn't open or it is not a VSAM data set.
6 | S,T | Access-method control block information about an index was to be shown or tested, but no index was opened with the data set.
7 | M,S | An exit list was to be modified or shown, but the exit indicated isn't present in the exit list. (With TESTCB, if the indicated exit isn't present, you get an unequal condition.)
8 | G | There isn't enough virtual storage in your program's address space to generate the access-method control block(s), exit list(s), or request parameter list(s) and no work area outside your address space was specified; or inconsistent use of AM=VTAM on list and execute forms (either AM=VTAM was specified on the list form and not on the execute form, or AM=VTAM was specified on the execute form and not on the list form).
9 | G | The work area specified was too small for generation or display of the indicated control block or fields.
10 | G,M | With GENCB, exit-list control-block type was specified and you specified an exit without giving an address. With MODCB, exit-list control-block type was specified and you specified an exit without giving an address; in this case, either active or inactive must be specified, but load cannot be specified.
11 | M | Either (1) a request parameter list was to be modified, but the request parameter list defines an asynchronous request that is active (that is, no CHECK or ENDREQ has been issued on the request) and thus cannot be modified, or (2) MODCB is already issued for the control block, but hasn't yet completed.
12 | M | An access-method control block was to be modified, but the data set identified by the access-method control block is open and thus cannot be modified.
13 | M | An exit list was to be modified, and you attempted to activate an exit without providing a new exit address. Because the exit list indicated does not contain an address for that exit, your request cannot be honored.
14 | G,M,T | One of the option codes (for MACRF, ATRB, or OPTCD) has an invalid combination of option codes specified (for example, OPTCD=(ADR,SKP)).
15 | G,S | The work area specified did not begin on a fullword boundary.
16 | G,M,S,T | A VTAM keyword or subparameter was specified but the AM=VTAM parameter was not specified. AM=VTAM must be specified in order to process a VTAM version of the control block.
18 | G,M,S,T | Two or more keywords of a mutually exclusive group were specified (for example, ARG and NIB).
19 | M,S,T | A keyword was specified which refers to a field beyond the length of the control block located at the address indicated (for example, a VTAM keyword, but the control block pointed to is a shorter, nonVTAM block).
20 | S | Keywords were specified which apply only if MACRF=LSR or GSR.

*G=GENCB, M=MODCB, S=SHOWCB, T=TESTCB

Figure 5. GENCB, MODCB, SHOWCB, and TESTCB Return Codes
ACB Macro (Generate an Access-Method Control Block)

Before you can open a data set for processing, you must create an access-method control block that identifies the data set to be opened, specifies the type of processing (for example, sequential processing) to be done, specifies basic options (for example, buffer size), and indicates whether exit routines are to be used while the data set is being processed.

The ACB macro can be used to build an access-method control block when the program is assembled. If you adopt a subsequent release of VSAM in which the format of a control block has changed and have generated access-method control blocks using the ACB macro, you will have to reassemble your program.

Values for ACB-macro operands can be specified as absolute numeric expressions, character strings, codes, and expressions that generate valid relocatable A-type address constants.

VSAM allows multiple access-method control blocks to gain access to the same data set and conserves resources by connecting those ACBs to the same control block structure. The ACBs must be in the same region, and they must be opening to the same base cluster. The connection occurs independently of the path selected to the base cluster.

Through MACRF options, you specify whether sharing is to be based on DDNAME (MACRF=DDN) or data set name (MACRF=DSN). If the DDN option is selected (or taken as the default), two ACBs that specify the same DDNAME will share the same control block structure. If the DSN option is selected, the new ACB will be connected to an existing control block structure if:

- The existing control block structure also specifies DSN and
- The new and existing control block structures have compatible processing options

To be compatible, both the new ACB and the existing control block structure must be consistent in their specification of the following processing options:

- Structure is an entry-sequenced data set
- Structure is a key-sequenced data set
- Structure has MACRF=DFR
- Structure has MACRF=UBF
- Structure has MACRF=ICI
- Structure has MACRF=LSR
- Structure has MACRF=GSR

Those options that apply to the existing structure must also be specified in the new ACB. Conversely, the options that apply to the new ACB must also be specified in the existing structure. For example, if the new ACB and the existing structure both specify MACRF=DFR, the connection will be made. If the new ACB specifies MACRF=DFR and the existing structure specifies MACRF=DFR,UBF, no connection will be made.

If compatibility cannot be established, OPEN tries (within the limitations of the share options specified when the data set was defined) to build a new control block structure. If it can’t, the OPEN fails.
The format of the ACB macro is:

<table>

</tbody>
</table>

where:

- **label** is one to eight characters that provides a symbolic address for the access-method control block that is assembled and also, if you omit the DDNAME operand, serves as the ddname.

- **AM=VSAM** specifies that the access method using this control block is VSAM.

- **BSTRNO=number** specifies the number of strings initially allocated for access to the base cluster of a path. The default is STRNO. BSTRNO is ignored if the object being opened is not a path. If the number specified for BSTRNO is insufficient, VSAM will dynamically extend the number of strings as needed for the access to the base cluster. BSTRNO can influence performance. The VSAM control blocks for the set of strings specified by BSTRNO are allocated on contiguous virtual storage, whereas this is not guaranteed for the strings allocated by dynamic extension.

- **BUFND=number** specifies the number of I/O buffers VSAM is to use for transmitting data between virtual and auxiliary storage. A buffer is the size of a control interval in the data component. The minimum number you may specify is 1 plus the number specified for STRNO (if you omit STRNO, BUFND must be at least 2, because the default for STRNO is 1). The number can be supplied by way of the JCL DD AMP parameter as well as by way of the macro. The default is the minimum number required.
**BUFNI=number**

specifies the number of I/O buffers VSAM is to use for transmitting the contents of index entries between virtual and auxiliary storage for keyed access. A buffer is the size of a control interval in the index. The minimum number is the number specified for STRNO (if you omit STRNO, BUFNI must be at least 1, because the default for STRNO is 1). You can supply the number by way of the JCL DD AMP parameter as well as by way of the macro. The default is the minimum number required.

**BUFSP=number**

specifies the maximum number of bytes of virtual storage to be used for the data and index I/O buffers. VSAM gets the storage in your program's address space. If you specify less than the amount of space that was specified in the BUFFERSPACE parameter of the DEFINE command when the data set was defined, VSAM overrides your BUFSP specification upward to the value specified in BUFFERSPACE. (BUFFERSPACE, by definition, is the least amount of virtual storage that will ever be provided for I/O buffers.) You can supply BUFSP by way of the JCL DD AMP parameter as well as by way of the macro. If you don't specify BUFSP in either place, the amount of storage used for buffer allocation is the largest of:

- the amount specified in the catalog (BUFFERSPACE),
- the amount determined from BUFND and BUFNI, or
- the minimum storage required to process the data set with its specified processing options

If BUFSP is specified and the amount is less than the minimum amount of storage required to process the data set, VSAM cannot open the data set.

A valid BUFSP amount takes precedence over the amount called for by BUFND and BUFNI. If the BUFSP amount is greater than the amount called for by BUFND and BUFNI, the extra space is allocated as follows:

- When MACRF indicates direct access only, additional index buffers are allocated.
- When MACRF indicates sequential access, one additional index buffer and as many data buffers as possible are allocated.

If the BUFSP amount is less than the amount called for by BUFND and BUFNI, the number of data and index buffers is decreased as follows:

- When MACRF indicates direct access only, the number of data buffers is decreased to not less than the minimum number. Then, if required, the number of index buffers is decreased until the amount called for by BUFND and BUFNI complies with the BUFSP amount.
- When MACRF indicates sequential access, the number of index buffers is decreased to not less than 1 more than the minimum number. Then, if required, the number of data buffers is decreased to not less than the minimum number. If still required, 1 more is subtracted from the number of index buffers.
- Neither the number of data buffers nor the number of index buffers is decreased to less than the minimum number.

If the index doesn't exist or isn't being opened, only BUFND, and not BUFNI, enters into these calculations.
The following examples show how VSAM uses your specifications to obtain storage:

Example 1: BUFSP not specified
BUFFERSPACE is 32768
BUFND is 24576 (Data control interval is 2048)
BUFNI is 10240 (Index control interval is 1024)
STRNO is 11
BUFFSP will be set to 35840 (the minimum needed to process the data set), since this is the largest value.

Example 2: BUFSP not specified
BUFFERSPACE is 24576
BUFND is 10240 (Data control interval is 1024)
BUFNI is 5120 (Index control interval is 512)
STRNO is 1
BUFFSP will be set to 24576, the BUFFERSPACE amount, since this is the largest value.

Example 3: BUFSP not specified
BUFFERSPACE is 32768
BUFND is 24576 (Data control interval is 2048)
BUFNI is 10240 (Index control interval is 1024)
STRNO is 5
BUFFSP will be set to 34816, the sum of BUFND and BUFNI, since this is the largest value.

Example 4: BUFSP is 30696
BUFFERSPACE is 30696
BUFND is 24576 (Data control interval is 2048)
BUFNI is 10240 (Index control interval is 1024)
STRNO is 6
MACRF=(KEY,DIR,OUT)
BUFFND will be reduced to 18432, and BUFNI remains the same, since the original BUFND and BUFNI are more than BUFSP.

Example 5: Same as example 4, except MACRF=(KEY,SEQ,OUT)
BUFFNI will be reduced to 7168 (for 1 more than the STRNO number of buffers), and BUFND will be reduced by 2048 to 22528, since the original BUFND and BUFNI are more than BUFSP.

**CATALOG=YES | NO**
specifies whether a catalog is being opened as a catalog (YES) or as a data set (NO). When NO is coded (or taken as the default), you can process the catalog with request macros. When YES is coded, a catalog must be processed with an SVC designed for that purpose.

**CRA=SCRA | UCRA**
specifies that a catalog recovery area is to be opened and that the control blocks are to be built in either system storage (SCRA) or user storage (UCRA). If you specify SCRA and issue record management requests, you must operate in key 0. If you specify UCRA, you must be authorized by the system and you must supply the master password of the master catalog.
DDNAME=ddname

is one to eight characters that identifies the data set that you want to process by specifying the JCL DD statement for the data set. You may omit DDNAME and provide it by way of the label or by way of the MODCB macro before opening the data set. MODCB is described later in this chapter.

EXLST=address

specifies the address of a list of addresses of exit routines that you are providing. The list is established by the EXLST or GENCB macro. If you use the EXLST macro, you can specify its label here as the address of the exit list. If you use GENCB, you can specify the address returned by GENCB in register 1 or the label of an area you supplied to GENCB for the exit list. Omitting this operand indicates that you have no exit routines. Exit routines are described in the chapter “User-Written Exit Routines.”

MACRF=([ADR][,CNV][,KEY]
[,CFX | NFX]
[,DDN | DSN]
[,DFR | NDF]
[,DIR][,SEQ][,SKP]
[,ICI | NCI]
[,IN][,OUT]
[,NIS | SIS]
[,NRM | AIX]
[,NRS | RST]
[,NSR | LSR | GSR]
[,NUB | UBF])

specifies the kind(s) of processing you will do with the data set. The options must be meaningful for the data set. For example, if you specify keyed access for an entry-sequenced data set, you cannot open the data set. You must specify all of the types of access you’re going to use, whether you use them concurrently or by switching from one to the other. Figure 6 gives the options; they are arranged in groups, and each group has a default value (indicated by underlining). You may specify options in any order. You may specify both ADR and KEY to process a key-sequenced data set. You may specify both DIR and SEQ; with keyed access, you may specify SKP as well. If you specify OUT and want simply to retrieve some records as well as update, delete, or insert others, you need not also specify IN.

MAREA=address

specifies the address of an optional OPEN/CLOSE/TCLOSE message area.

MLEN=number

specifies the length of an optional OPEN/CLOSE/TCLOSE message area. Default=0; maximum=32K.

PASSWD=address

specifies the address of a field that contains the highest-level password required for the type(s) of access indicated by the MACRF operand. The first byte of the field pointed to contains the length (in binary) of the password (maximum of 8 bytes). Zero indicates that no password is supplied. If the data set is password-protected and you don’t supply a required password in the access-method control block, VSAM gives the console operator the opportunity to supply it when you open the data set.

<sup>1</sup> Described in OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications

**Figure 6.** MACRF Options

**STRNO=number**

specifies the number of requests requiring concurrent data-set positioning VSAM is to be prepared to handle. The default is 1. A request is defined by a given request parameter list or chain of request parameter lists. See "RPL Macro (Generate a Request Parameter List)" and "GENCB Macro (Generate a Request Parameter List)" later in this chapter for information on request parameter lists. When records are loaded into an empty data set, the STRNO value in the access-method control block must be 1.

OS/VS dynamically extends the number of strings as needed by concurrent requests for this ACB, and this automatic extension can influence performance. The VSAM control blocks for the set of strings specified by STRNO are allocated on contiguous virtual storage, but this is not guaranteed for the strings allocated by dynamic extension.
You could specify for STRNO the total number of request parameter lists or chains of request parameter lists that you are using to define requests. (VSAM needs to remember only one position for a chain of request parameter lists.) However, each position beyond the minimum number that VSAM needs to be able to remember requires additional virtual storage space for:

- A minimum of one data I/O buffer and, for keyed access, one index I/O buffer (the size of an I/O buffer is the control-interval size of a data set)
- Internal control blocks and other areas

Example: ACB Macro

In this example, the ACB macro is used to identify a data set to be opened and to specify the types of processing to be performed. The access-method control block generated by this example is built when the program is assembled.

```
BLOCK ACB AM=VSAM, BUFND=4, BUFNI=3, BUFSP=19456, DDNAME=DATASETS, EXLST=EXITS, MACRF=(KEY,DIR, SEQ,OUT), PASSWD=FIELD, STRNO=2
FIELD DC FL1 '6', C 'CHANGE' The update password: CHANGE has 6 characters.
```

The ACB macro's operands are:

- BUFND, BUFNI, and BUFSP, which specify four I/O buffers for data; three I/O buffers for index entries; and 19,456 bytes of buffer space, enough space to accommodate control intervals of data that are 4096 bytes and control intervals of index entries that are 1024 bytes.
- DDNAME, which specifies that this access-method control block is associated with a DD statement named DATASETS.
- EXLST, which specifies that the exit list associated with this access-method control block is named EXITS.
- MACRF, which specifies keyed-direct and keyed-sequential processing for both insertion and update.
- PASSWD, which specifies the location, FIELD, of the password provided. FIELD contains the length of the password as well as the password itself.
- STRNO, which specifies that two requests will require concurrent positioning.
EXLST Macro (Generate an Exit List)

The EXLST macro is used to generate an exit list when the program is assembled. See the chapter “User-Written Exit Routines” for a description of the exit routines. The EXLST macro is coordinated with the EXLST operand of an ACB or GENCB macro used to generate an ACB: you must code the EXLST operand to make use of the exit list. One or more access-method control blocks may use the same exit list—the exit routines indicated by the list would do the exit processing for the data sets identified by the control blocks.

Values for EXLST macro operands can be specified as absolute numeric expressions, character strings, codes, and expressions that generate valid relocatable A-type address constants.

The format of the EXLST macro is:

```
[ label ] EXLST [AM=VSAM]
[,EODAD=(address [,A | N][,L])]
[,JRNAD=(address [,A | N][,L])]
[,LERAD=(address [,A | N][,L])]
[,SYNAD=(address [,A | N][,L])]
```

where:

- **label**
  is one to eight characters that provides a symbolic address for the exit list that is established.

- **AM=VSAM**
  specifies that the access method using the control block is VSAM.

- **EODAD=(address [,A | N][,L])**
  specify that you are supplying a routine for the exit specified. The exits and values that can be specified for them are:

  **EODAD**
  specifies that an exit is provided for special processing when the end of a data set is reached by sequential access.

  **JRNAD**
  specifies that an exit is provided for journalizing as you process data records.

  **LERAD**
  specifies that an exit is provided for analyzing logical errors.

  **SYNAD**
  specifies that an exit is provided for analyzing physical errors.

- **address**
  is the address of a user-supplied exit routine. The address must immediately follow the equal sign.

- **A | N**
  specifies that the exit routine is active (A) or not active (N). VSAM does not enter a routine whose exit is marked not active.
L specifies that the address is the address of an eight-byte field that contains the name of an exit routine in a partitioned data set that is identified by a JOBLIB or STEPLIB DD statement or in SYS1.LINKLIB. VSAM is to load the exit routine for exit processing. If L is omitted, the address gives the entry point of the exit routine in virtual storage. L may precede or follow the A or N specification.

Example: EXLST Macro

In this example, an EXLST macro is used to identify exit routines that are provided for analyzing logical and physical errors. The label, EXITS, of the EXLST macro is used in an ACB or GENCB macro that generates an access-method control block to associate the exit list with an access-method control block. The exit list generated by this example is built when the program is assembled.

```
EXITS EXLST EODAD=(ENDUP,N), LERAD=LOGICAL, SYNAD=(ROUTNAME, L)
```

ENDUP          EODAD routine.
LOGICAL       LERAD routine.
ROUTNAME DC    Pad shorter names with blanks: C'SYN' or CL8'SYN'.
                C'PHYSICAL'

The EXLST macro's operands are:

- **EODAD**, which specifies that the end-of-data routine is located at ENDUP and is not active.
- **LERAD**, which specifies that the logical-error routine is located at LOGICAL and is active.
- **SYNAD**, which specifies that the physical-error routine's name is located at ROUTNAME.

RPL Macro (Generate a Request Parameter List)

After you have connected your program to the data set, you can issue requests for access to it. A request parameter list defines a request. Each request macro (GET, PUT, ERASE, POINT, CHECK, and ENDREQ) gives the address of the request parameter list that defines it. See the chapter "Request Macros" for information on these macros.

The RPL macro can be used to generate a request parameter list when your program is assembled. The operands of the RPL macro are optional in some cases, but required in others. It is not necessary to omit operands that are not required for a request; they are ignored. Thus, for example, if you switch from direct to sequential retrieval with a request parameter list, you don't have to zero out the address of the field containing the search argument (ARG=address).

Values for RPL-macro operands can be specified as absolute numeric expressions, character strings, codes, and expressions that generate valid relocatable A-type address constants.

Request parameter lists can be linked together in a chain. A request macro points to the first request parameter list, which points to the second, and so on. The effect of chaining request parameter lists is to cause a single request...
macro to operate on multiple records. For example, if a GET macro points to a chain of five request parameter lists, five records can be retrieved with a single GET.

The format of the RPL macro is:

```
[ label ]  RPL  [ ACB=address ]
            [ AM=VSAM ]
            [ AREA=address ]
            [ AREALEN=number ]
            [ ARG=address ]
            [ ECB=address ]
            [ KEYLEN=number ]
            [ MSGAREA=address ]
            [ MSGLEN=number ]
            [ NXTRPL=address ]
            [ OPTCD=( [ADR | CNV | KEY]
            [ ,DIR | SEQ | SKP ]
            [ ,ARD | LRD ]
            [ ,FWD | BWD ]
            [ ,ASY | SYN ]
            [ ,NSP | NUP | UPD ]
            [ ,KEQ | KGE ]
            [ ,FKS | GEN ]
            [ ,LOC | MVE ] ) ]
            [ RECLEN=number ]
            [ TRANSID=number ]
```

where:

- **label**
  is one to eight characters that provides a symbolic address for the request parameter list that is generated. You can use it in the request macros to give the address of the list. You can use it in the NXTRPL operand of the RPL macro, when you are chaining request parameter lists, to indicate the next list.

- **ACB=address**
  specifies the address of the access-method control block that identifies the data set to which access will be requested. If you used the ACB macro to generate the control block, you may specify the label of that macro for the address. If the ACB operand is not coded, you must specify the address before issuing the request.

- **AM=VSAM**
  specifies that the access method using the control block is VSAM.

- **AREA=address**
  specifies the address of a work area to and from which VSAM moves a data record if you request it to do so (with the RPL operand OPTCD=MVE). If your request is to process records in the I/O buffer (OPTCD=LOC), VSAM puts into this work area the address of a data record within the I/O buffer.
AREALEN=number
specifies the length, in bytes, of the work area whose address is specified by the AREA operand. Its minimum for OPTCD=MVE is the size of a data record (of the largest data record, for a data set with records of variable length). For OPTCD=LOC the area should be 4 bytes to contain the address of a data record within the I/O buffer.

ARG=address
specifies the address of a field that contains the search argument for direct retrieval, skip-sequential retrieval, and positioning. For keyed access (OPTCD=KEY), the search argument is a full or generic key or relative record number; for addressed access (OPTCD=ADR), it is an RBA. If you specify a generic key (OPTCD=GEN), you must also specify in the KEYLEN operand how many of the bytes of the full key you are using for the generic key.

ECB=address
specifies the address of an event control block (ECB) that you may supply. VSAM indicates in the ECB whether a request is complete or not (using standard OS/VS completion codes, which are described in OS/VS1 System Data Areas and OS/VS2 Data Areas). This operand is always optional.

KEYLEN=number
specifies the length, in bytes, of the generic key (OPTCD=GEN) you are using for a search argument (given in the field addressed by the ARG operand). This operand is specified as a number from 1 through 255; it is required when the search argument is a generic key. For full-key searches, VSAM knows the key length, which is taken from the catalog definition of the data set when you open the data set.

MSGAREA=address
specifies the address of an area that you may optionally supply for VSAM to send you a message in case of a physical error. The format of a physical-error message is given under “Physical Errors” in the chapter “Request Macros.”

MSGLEN=number
specifies the size, in bytes, of the message area indicated in the MSGAREA operand. If MSGAREA is specified, MSGLEN is required. The size of a message is 128 bytes; if you provide less than 128 bytes, no message is returned to your program.

NXTRPL=address
specifies the address of the next request parameter list in a chain. Omit this operand from the macro that generates the last list in the chain. When you issue a request that is defined by a chain of request parameter lists, indicate in the request macro the address of the first parameter list in the chain.
OPTCD=([ADR | CNV | KEY]
  [,DIR | SEQ | SKP]
  [,ARD | LRD]
  [,FWD | BWD]
  [,ASY | SYN]
  [,NSP | NUP | UPD]
  [,KEQ | KGE]
  [,FKS | GEN]
  [,LOC | MVE])
specifies the options that govern the request defined by the request parameter list. Each group of options has a default; options are shown in Figure 7 with defaults underlined. Only one option from each group can be specified. Some requests do not require an option from all of the groups to be specified. The groups that aren't required are ignored; thus, you can use the same request parameter list for a combination of requests (GET, PUT, POINT, for example) without zeroing out the inapplicable options each time you go from one request to another.

RECLLEN=number
specifies the length, in bytes, of a data record being stored. This parameter is required for a PUT request.

For GET requests, VSAM puts the length of the record retrieved in this field in the request parameter list. It will be there if you update and store the record.

TRANSID=number
specifies a number that relates modified buffers in a buffer pool. Used in shared resource applications and described in OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications.

You can use the ECB to determine that an asynchronous request is complete before issuing a CHECK macro. (If you issue a CHECK before a request is complete, you give up control and must wait for completion.) You can also test for completion with the TESTCB I/O=COMPLETE operand. TESTCB is described later in this chapter.

Each request parameter list in a chain should have the same OPTCD options. Having different options may cause logical errors. You can't chain request parameter lists for updating or deleting records—only for retrieving records or storing new records. You can't process records in the I/O buffer with chained request parameter lists. (OPTCD=UPD and LOC are invalid for a chained request parameter list.)

With chained request parameter lists, a POINT, a sequential or skip-sequential GET, or a direct GET with positioning requested (OPTCD=NSP) causes VSAM to position itself at the record following the record identified by the last request parameter list in the chain.

Figure 7. OPTCD Options
Example: RPL Macro

In this example, an RPL macro is used to generate a request parameter list named PARMLIST.

```
ACCESS ACB MACRF=(SKP,OUT),
        DDNAME=PAYROLL

PARMLIST RPL ACB=ACCESS,
        AM=VSAM,
        AREA=WORK,
        AREALEN=125,
        ARG=SEARCH,
        OPTCD=(SKP,UPO)

WORK DS CL125
SEARCH DS CL8
MESSAGE DS CL128
```

Most OPTCD defaults are appropriate to assumptions.

The ACB macro, named ACCESS, specifies skip-sequential retrieval for update. Further details may be provided on a DD statement named PAYROLL.

The RPL macro’s operands are:

- **ACB**, which associates the request parameter list with the access-method control block generated by ACCESS.
- **AREA** and **AREALEN**, which specify a work area, WORK, that is 125 bytes long.
- **ARG**, which specifies that the search argument is defined at SEARCH. The search argument is eight bytes long.
- **MSGAREA** and **MSGLEN**, which specify a message area, MESSAGE, that is 128 bytes long. The message area is provided for physical-error messages.
- **OPTCD**, which specifies skip-sequential processing and specifies that a retrieved record may be updated or deleted.

Because KEYLEN is not coded, a full-key search is assumed.

GENCB Macro (Generate an Access-Method Control Block)

Before you can open a data set for processing, you must create an access-method control block that identifies the data set to be opened, specifies the type of processing (for example, sequential processing) to be done, specifies basic options (for example, buffer size), and indicates whether exit routines are to be used while the data set is being processed.

The GENCB macro is used to build an access-method control block when the program is executed. Generation at execution has the advantage of requiring no reassembly of a program when you adopt a new version of VSAM in which control block formats might have changed.
The operands of the GENCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. "Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB" gives all the ways of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter for information on the return codes used to indicate whether the GENCB request was successful.

The format of the GENCB macro used to generate an access-method control block is:

<table>

|         |       | [,MAREA=address] |
|         |       | [,MLEN=number] |
|         |       | [,PASSWD=address] |
|         |       | [,STRNO=number] |
|         |       | [,WAREA=address] |

where:

*label*

is one to eight characters that provides a symbolic address for the GENCB macro.

**BLK=ACB**

specifies that you are generating an access-method control block.

**AM=VSAM**

specifies that the access method using this control block is VSAM.
BSTRNO=number
specifies the number of strings initially allocated for access to the base cluster of a path. The default is STRNO. BSTRNO is ignored if the object being opened is not a path. If the number specified for BSTRNO is insufficient, VSAM will dynamically extend the number of strings as needed for the access to the base cluster. BSTRNO can also influence performance. The VSAM control blocks for the set of strings specified by BSTRNO are allocated on contiguous virtual storage, whereas this is not guaranteed for the strings allocated by dynamic extension.

BUFND=number
specifies the number of I/O buffers VSAM is to use for transmitting data between virtual and auxiliary storage. A buffer is the size of a control interval in the data component. The minimum number you may specify is 1 plus the number specified for STRNO (if you omit STRNO, BUFND must be at least 2, because the default for STRNO is 1). The number can be supplied by way of the JCL DD AMP parameter as well as by way of the macro. The default is the minimum number required. A larger number for BUFND can improve the performance of sequential access.

BUFNI=number
specifies the number of I/O buffers VSAM is to use for transmitting index entries between virtual and auxiliary storage for keyed access. A buffer is the size of a control interval in the index. The minimum number is the number specified for STRNO (if you omit STRNO, BUFNI must be at least 1, because the default for STRNO is 1). You can supply the number by way of the JCL DD AMP parameter as well as by way of the macro. The default is the minimum number required. A larger number for BUFNI can improve the performance of keyed-direct retrieval.

BUFSP=number
specifies the maximum number of bytes of virtual storage to be used for the data and index I/O buffers. VSAM gets the storage in your program's address space. If you specify less than the amount of space that was specified in the BUFFERSPACE parameter of the DEFINE command when the data set was defined, VSAM overrides your BUFSP specification upward to the value specified in BUFFERSPACE. (BUFFERSPACE, by definition, is the least amount of virtual storage that will ever be provided for I/O buffers.) You can supply BUFSP by way of the JCL DD AMP parameter as well as by way of the macro. If you don't specify BUFSP in either place, the amount of storage used for buffer allocation is the largest of:

- the amount specified in the catalog (BUFFERSPACE),
- the amount determined from BUFND and BUFNI, or
- the minimum storage required to process the data set with its specified processing options

If BUFSP is specified and the amount is less than the minimum amount of storage required to process the data set, VSAM cannot open the data set.

A valid BUFSP amount takes precedence over the amount called for by BUFND and BUFNI. If the BUFSP amount is greater than the amount called for by BUFND and BUFNI, the extra space is allocated as follows:

- When MACRF indicates direct access only, additional index buffers are allocated.
When MACRF indicates sequential access, one additional index buffer and as many data buffers as possible are allocated.

If the BUFSP amount is less than the amount called for by BUFND and BUFNI, the number of data and index buffers is decreased as follows:

- When MACRF indicates direct access only, the number of data buffers is decreased to not less than the minimum number. Then if required, the number of index buffers is decreased until the amount called for by BUFND and BUFNI complies with the BUFSP amount.
- When MACRF indicates sequential access, the number of index buffers is decreased to not less than 1 more than the minimum number. Then, if still required, 1 more is subtracted from the number of index buffers.
- Neither the number of data buffers nor the number of index buffers is decreased to less than the minimum number.

If the index doesn't exist or isn't being opened, only BUFND, and not BUFNI, enters into these calculations.

**CATALOG=**YES | NO

specifies whether a catalog is being opened as a catalog (YES) or as a data set (NO). When NO is coded (or taken as the default), you can process the catalog with request macros. When YES is coded, a catalog must be processed with an SVC designed for that purpose.

**COPIES=**number

specifies the number of copies of the access-method control block VSAM is to generate. All of the copies are identical. You can use MODCB to tailor each one for the data set and processing you want for it. MODCB is described in this chapter.

**CRA=**SCRA | UCRA

specifies that a catalog recovery area is to be opened and that the control blocks are to be built in either system storage (SCRA) or user storage (UCRA). If you specify SCRA and issue record management requests, you must operate in key 0. If you specify UCRA, you must be authorized by the system and you must supply the master password of the master catalog.

**DDNAME=**ddname

is one to eight characters that identifies the data set that you want to process by specifying the JCL DD statement for the data set. You may omit DDNAME and provide it by way of the MODCB macro before opening the data set. MODCB is described later in this chapter.

**EXLST=**address

specifies the address of a list of addresses of exit routines that you are providing. The list is established by the EXLST or GENCB macro. If you use the EXLST macro, you can specify its label here as the address of the exit list. If you use GENCB, you can specify the address returned by GENCB in register 1. Omitting this operand indicates that you have no exit routines. Exit routines are described in the chapter "User-Written Exit Routines."

**LENGTH=**number

specifies the length, in bytes, of the area, if any, that you are supplying for VSAM to generate the access-method control block(s). (See the WAREA operand.)
MACRF=(ADR,CNV,KEY)
               (CFX,NFX)
               (DDN,DSN)
               (DFR,NDF)
               (DIR,SEQ,SKP)
               (ICI,NCI)
               (IN,OUT)
               (NIS,SIS)
               (NRM,AIX)
               (NRS,RST)
               (NSR,LSR,GSR)
               (NUB,UBF))

specifies the kind(s) of processing you will do with the data set. The
options must be meaningful for the data set. For example, if you specify
keyed access for an entry-sequenced data set, you cannot open the data
set. You must specify all of the types of access you're going to use,
whether you use them concurrently or by switching from one to the other.
The options are shown earlier in Figure 6; they are arranged in groups, and
each group has a default value (indicated by underlining). You may specify
options in any order. You may specify both ADR and KEY to process a
key-sequenced data set. You may specify both DIR and SEQ; with keyed
access, you may specify SKP as well. If you specify OUT and want simply
to retrieve some records as well as update, delete, or insert others, you
need not also specify IN.

MAREA=address

specifies the address of an optional OPEN/CLOSE/TCLOSE message
area.

MLEN=number

specifies the length of an optional OPEN/CLOSE/TCLOSE message
area.

PASSWD=address

specifies the address of a field that contains the highest-level password
required for the type(s) of access indicated by the MACRF operand. The
first byte of the field contains the length (in binary) of the password
(maximum of 8 bytes). Zero indicates that no password is supplied. If the
data set is password-protected and you don't supply a required password in
the access-method control block, VSAM gives the console operator the
opportunity to supply it when you open the data set.

STRNO=number

specifies the number of requests requiring concurrent data-set positioning
VSAM is to be prepared to handle. A request is defined by a given request
parameter list or chain of request parameter lists. See “RPL Macro
(Generate a Request Parameter List)” and “GENCB Macro (Generate a
Request Parameter List)” in this chapter for information on request
parameter lists.

WAREA=address

specifies the address of an area in which the access-method control
block(s) is to be generated. (Otherwise VSAM obtains virtual-storage
space for the area and returns its address to you in register 1 and its length
in register 0.) The area must begin on a fullword boundary. This operand is
paired with the LENGTH operand, which must be given if you specify an
area address.
If you did not specify an area in which the access-method control block was to be generated, VSAM returns to your program the address of the area containing the control block(s) in register 1 and the length of the area in register 0. You can find out the length of each control block by dividing the length of the area by the number of copies. The address of each control block can then be calculated by this offset from the address in register 1. You can find the length of an access-method control block with the SHOWCB macro. SHOWCB is described later in this chapter.

If you are generating control blocks by issuing several GENCBs, specifying an area (WAREA and LENGTH parameters) for them enables you to address all of them with one base register and to avoid repetitive requests for virtual storage.

Example: GENCB Macro (Generate an Access-Method Control Block)

In this example, a GENCB macro is used to identify a data set to be opened and to specify the types of processing to be performed. The access-method control block generated by this example is built when the program is executed.

```
GENCB GENCB BLK=ACB, AM=VSAM,
BUFND=4, BUFNI=3,
BUFSP=19456,
DDNAME=DATASETS,
EXLST=EXITS,
MACRF=(KEY, DIR,
SEQ, OUT),
PASSWD=FIELD,
STRNO=2
ST 1, ACBADDR
ACBADDR DS F
FIELD DC FL1 '6', C 'CHANGE'
```

The GENCB macro's operands are:

- **BUFND, BUFNI, and BUFSP**, which specify four I/O buffers for data; three I/O buffers for index entries; and 19,456 bytes of buffer space, enough space to accommodate control intervals of data that are 4096 bytes and of index entries that are 1024 bytes.

- **DDNAME**, which specifies that this access-method control block is associated with a DD statement named DATASETS.

- **EXLST**, which specifies that the exit list associated with this access-method control block is named EXITS.

- **MACRF**, which specifies keyed direct and keyed sequential processing for both insertion and update.

- **PASSWD**, which specifies the location, FIELD, of the password provided.

- **STRNO**, which specifies that two requests will require concurrent positioning.
GENCB Macro (Generate an Exit List)

The GENCB macro can be used to generate an exit list when the program is executed. The GENCB macro is coordinated with the EXLST operand of the ACB or GENCB macro used to generate an access-method control block to make use of the exit list. One or more access-method control blocks may use the same exit list—the exit routines indicated by the list would do all the exit processing for the data sets identified by the control blocks.

The operands of the GENCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter for information on return codes used to indicate whether the GENCB request was successful.

The format of the GENCB macro used to generate an exit list is:

```
[label] GENCB [BLK=EXLST]
[,AM=VSAM]
[,EODAD=(address [,A | N][,L])]
[,JRNAD=(address [,A | N][,L])]
[,LERAD=(address [,A | N][,L])]
[,SYNAD=(address [,A | N][,L])]
[,COPIES=number]
[,LENGTH=number]
[,WAREA=address]
```

where:

- **label**
  - is one to eight characters that provides a symbolic address for the GENCB macro.

- **BLK=EXLST**
  - specifies that you are generating an exit list.

- **AM=VSAM**
  - specifies that the access method using this control block is VSAM.

- **EODAD=(address [,A | N][,L])**
- **JRNAD=(address [,A | N][,L])**
- **LERAD=(address [,A | N][,L])**
- **SYNAD=(address [,A | N][,L])**

specify that you are supplying a routine for the exit named. If none of these is specified, VSAM generates an exit list with inactive entries for all of the exits. The exits and values that can be specified for them are:

- **EODAD**
  - specifies that an exit is provided for special processing when the end of a data set is reached by sequential access.

- **JRNAD**
  - specifies that an exit is provided for journalizing as you process data records.
LERAD
 specifies that an exit is provided for analyzing logical errors.

SYNAD
 specifies that an exit is provided for analyzing physical errors.

address
 is the address of a user-supplied exit routine. The address must immediately follow the equal sign.

A | N
 specifies that the exit routine is active (A) or not active (N). VSAM does not enter a routine whose exit is marked not active.

L
 specifies that the address is the address of an eight-byte field that contains the name of an exit routine in a partitioned data set that is identified by a JOBLIB or STEPLIB DD statement or in SYS1.LINKLIB. VSAM is to load the exit routine for exit processing. If L is omitted, the address gives the entry point of the exit routine in virtual storage. L may precede or follow the A or N specification.

COPIES = number
 specifies the number of copies of the exit list you want generated. GENCB generates as many copies as you specify (default is 1) when your program is executed. All of the copies are the same. You can use MODCB to change some or all of the addresses in a list. MODCB is described later in this chapter.

LENGTH = number
 specifies the length, in bytes, of the area, if any, that you are supplying for VSAM to generate the exit list(s). (See the WAREA operand.)

WAREA = address
 specifies the address of an area in which the exit list(s) is to be generated. (Otherwise VSAM obtains virtual-storage space for the area and returns its address in register 1 and its length in register 0.) The area must begin on a fullword boundary. This operand is paired with the LENGTH operand, which must be given if you specify an area address.

If you do not specify an area in which the exit list is to be generated, VSAM returns to your program the address of the area in which the exit list(s) is generated in register 1, and the length of the area in register 0. You can find out the length of each exit list by dividing the length of the area by the number of copies. The address of each exit list can then be calculated by this offset from the address in register 1. You can find the length of an exit list with the SHOWCB macro, described under "SHOWCB Macro (Display an Exit List)" later in this chapter.

If you are generating control blocks by issuing several GENCBs, specifying an area (WAREA and LENGTH) for them enables you to address all of them with one base register and to avoid repetitive requests for virtual storage.
Example: GENCB Macro (Generate an Exit List)

In this example, a GENCB macro is used to generate an exit list when the program is executed.

```plaintext
EXITS GENCB BLK=EXLST,
      EODAD=(EOD,N),
      LERAD=LOGICAL,
      SYNAD=(ERROR,
             A,L)
      ST       1, EXLSTADR
      EOD      Address of the exit list is saved.
      LOGICAL  EODAD routine.
      ERROR    LERAD routine.
      DC       C'PHYSICAL' Name of the SYNAD module.
      EXLSTADR DS       F  Save area for exit-list address.
```

The GENCB macro's operands are:

- **BLK**, which specifies that an exit list is to be generated.
- **EODAD**, which specifies that the end-of-data routine is located at EOD and is not active.
- **LERAD**, which specifies that the logical-error routine is located at LOGICAL; because neither A nor N is specified, the LERAD routine is marked active by default.
- **SYNAD**, which specifies that the physical-error routine's name is located at ERROR.

Because no area was specified in which the exit list was to be generated, VSAM obtained virtual storage for the exit list and returned the address in register 1. Immediately after the GENCB macro, the address of the exit list, contained in register 1, is moved to EXLSTADR. EXLSTADR may be specified in a GENCB macro that generates an access-method control block or in a MODCB, SHOWCB, or TESTCB macro that modifies, displays, or tests fields in an exit list.

GENCB Macro (Generate a Request Parameter List)

After you have connected your program to the data set, you can issue requests for access to it. A request parameter list defines a request. Each request macro (GET, PUT, ERASE, POINT, CHECK, and ENDREQ) gives the address of a request parameter list that defines the request.

The GENCB macro can be used to generate the request parameter list when the program is executed. Using the GENCB macro gives you independence from possible changes in the format of the request parameter list in future releases of VSAM. It also gives you the ability to generate many copies of the list.

If you use GENCB to generate request parameter lists as you need them, and later free the space, you should first issue the ENDREQ macro for each request parameter list to free the VSAM resources used for keeping track of positions in the data set.

The operands of the GENCB macro to generate a request parameter list are optional in some cases, but required in others. It is not necessary to omit operands that are not required for a request; they are ignored. Thus, for
example, if you switch from direct to sequential retrieval with a request parameter list, you don’t have to zero out the address of the field containing the search argument (ARG=address).

The operands of the GENCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. "Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB" gives all the ways of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter for information on the return codes used to indicate whether the GENCB request was successful.

The format of the GENCB macro used to generate a request parameter list is:

<table>

</table>

where:

*label* is one to eight characters that provides a symbolic address for the GENCB macro. See the discussion of the COPIES operand for addressing lists generated by GENCB.

**BLK=RPL** specifies that you are generating a request parameter list.
ACB=address
specifies the address of the access-method control block that identifies the
data set to which access will be requested. If you omit this operand, you
must issue MODCB to specify the address of the access-method control
block before you issue a request. MODCB is described later in this
chapter.

AM=VSAM
specifies that the access method using this control block is VSAM.

AREA=address
specifies the address of a work area to and from which VSAM moves a
data record if you request it to do so (with the RPL operand
OPTCD=MVE). If you request to process records in the I/O buffer
(OPTCD=LOC), VSAM puts into this work area the address of a data
record within the I/O buffer.

AREALEN=number
specifies the length, in bytes, of the work area whose address is specified
by the AREA operand. Its minimum for OPTCD=MVE is the size of a
data record (of the largest data record, for a data set with records of
variable length). For OPTCD=LOC the area should be 4 bytes to contain
the address of a data record within the I/O buffer.

ARG=address
specifies the address of a field that contains the search argument for direct
retrieval, skip-sequential retrieval, and positioning. For keyed access
(OPTCD=KEY), the search argument is a full or generic key; for
addressed access (OPTCD=ADR), it is an RBA. If you specify a generic
key (OPTCD=GEN), you must also specify in the KEYLEN operand how
many of the bytes of the full key you are using for the generic key.

COPIES=number
specifies the number of copies of the request parameter list you want
generated. GENCB generates as many copies as you specify (default is 1)
when your program is executed.

The copies of a request parameter list can be used to:
- Chain lists together to gain access to many records with one request.
- Define many requests to gain access to many parts of a data set
  concurrently.

All of the copies generated are identical; you have to use MODCB to tailor
them to specific requests. MODCB is described in this chapter.

ECB=address
specifies the address of an event control block (ECB) that you may supply.
VSAM indicates in the ECB whether a request is complete or not (using
standard OS/VS completion codes, which are described in OS/VS1
System Data Areas, and OS/VS2 Data Areas). This operand is always
optional.

KEYLEN=number
specifies the length, in bytes, of the generic key (OPTCD=GEN) you are
using for a search argument (given in the field addressed by the ARG
operand). This operand is required with a search argument that is a generic
key. The number can be 1 through 255. For full-key searches, VSAM
knows the key length, which is taken from the catalog definition of the
data set when you open the data set.
LENGTH = number
specifies the length, in bytes, of the area, if any, that you are supplying for VSAM to generate the request parameter list(s). (See the WAREA operand.) You can find out how long a request parameter list is with the SHOWCB macro, described later in this chapter.

MSGAREA = address
specifies the address of an area that you are supplying for VSAM to send you a message in case of a physical error. The format of a physical-error message is given under “Physical Errors” in the chapter “Request Macros.” This operand is always optional.

MSGLEN = number
specifies the size, in bytes, of the message area indicated in the MSGAREA operand. The size of a message is 128 bytes; if you provide less than 128 bytes, no message is returned to your program. This operand is required when MSGAREA is coded.

NXTRPL = address
specifies the address of the next request parameter list in a chain. Omit this operand from the macro that generates the only or last list in the chain. When you issue a request that is defined by a chain of request parameter lists, indicate in the request macro the address of the first parameter list in the chain. A single request macro can be defined by multiple request parameter lists, such that a GET, for example, can cause VSAM to retrieve two or more records.

OPTCD = ([ADR | CNV | KEY]
[.DIR | SEQ | SKP]
[.ARD | LRD]
[.FWD | BWD]
[.ASY | SYN]
[.NSP | NUP | UPD]
[.KEQ | KGE]
[.FKS | GEN]
[.LOC | MVE])
specifies the options that govern the request defined by the request parameter list. Each group of options has a default; options are shown earlier in Figure 7 with defaults underlined. Only one option from each group is effective for a request. Some requests do not require an option from all of the groups to be specified. The groups that aren’t required are ignored; thus, you can use the same request parameter list for a combination of requests (GET, PUT, POINT, for example) without zeroing out the inapplicable options each time you go from one request to another.

RECLEN = number
specifies the length, in bytes, of a data record being stored. With fixed-length records, set it and forget it. This operand is required for PUT requests. For GET requests, VSAM puts the length of the record retrieved in this field in the request parameter list. It will be there if you update and store the record.

TRANSID = number
specifies a number that relates modified buffers in a buffer pool. Used in shared resource applications and described in OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications.
`WAREA=address` specifies the address of an area in which the request parameter list(s) is to be generated. (Otherwise VSAM obtains virtual-storage space for the area and returns its address to you in register 1 and its length in register 0.) The area must begin on a fullword boundary. This operand is paired with the `LENGTH` operand, which must be given if you specify an area address.

If you do not specify an area in which the request parameter list is to be generated, VSAM returns to your program the address of the area in which the request parameter list(s) was generated in register 1, and the length of the area in register 0. You can find the length of each list by dividing the length of the area by the number of copies. You can then calculate the address of each list by using the length of each list as an offset.

If you are generating control blocks by issuing several GENCBs, specifying an area (WAREA and LENGTH parameters) for them enables you to address all of them with one base register and to avoid repetitive requests for virtual storage.

You can use the ECB to determine that an asynchronous request is complete before issuing a CHECK macro. (If you issue a CHECK before a request is complete, you give up control and must wait for completion.) You can also test for completion with the TESTCB I/O=COMPLETE operand.

When GENCB is used to build a chain of request parameter lists, the request parameter lists may be chained using only GENCB macros or using GENCB and MODCB macros together. When only GENCB is used, the request parameter lists are created in reverse order, as follows:

SECOND GENCB BLK=RPL
LR 2,1
FIRST GENCB BLK=RPL,NXTRPL=(2)

SECOND GENCB creates the second request parameter list, which makes its address available for the first request parameter list. The address of the request parameter list is returned in register 1 and is loaded into register 2. FIRST GENCB creates the first request parameter list and supplies the address of the next request parameter list using register notation. GENCB and MODCB macros may be used together to create a chain of request parameter lists, as follows:

GENCB BLK=RPL,COPIES=2
LR 2,0
SRL 2,1
LR 3,1
LA 4,0(2,3)
MODCB RPL=(3),NXTRPL=(4)

The GENCB macro creates two request parameter lists. The length of the parameter lists is returned in register 0 and loaded into register 2. The address of the area in which the lists were created (and, therefore, the address of the first one) is returned in register 1 and loaded into register 3. The SRL statement divides the total length of the area (register 2) by 2. The LA statement loads the address of the second request parameter list into register 4. The MODCB macro modifies the first request parameter list (register 3) by supplying the address of the second request parameter list (register 4) in the NXTRPL operand.

Each request parameter list in a chain should have the same OPTCD options. Having different options may cause logical errors. You can’t chain request parameter lists for updating or deleting records—only for retrieving records or storing new records. You can’t process records in the I/O buffer with
chained request parameter lists. (OPTCD=UPD and LOC are invalid for a chained request parameter list.)

With chained request parameter lists, a POINT, a sequential or skip-sequential GET, or a direct GET with positioning requested (OPTCD=NSP) causes VSAM to position itself at the record following the record identified by the last request parameter list in the chain.

Example: GENCB Macro (Generate a Request Parameter List)

In this example, a GENCB macro is used to generate a request parameter list.

```

       OPTCD=(SKP,UPD)

ACCESS ACB MACRF=(SKP,OUT)
WORK DS CL125
SEARCH DS CL8
MESSAGE DS CL128
```

The GENCB macro's operands are:
- **BLK**, which specifies that a request parameter list is to be generated.
- **ACB**, which specifies that the request parameter list is associated with a data set and processing options identified by ACCESS.
- **AREA** and **AREALEN**, which specify a 125-byte work area to be used for processing records.
- **ARG**, which specifies the address of the search argument.
- **MSGAREA** and **MSGLEN**, which specify a 128-byte area to be used for physical-error messages.
MODCB Macro (Modify an Access-Method Control Block)

The MODCB macro can be used to modify the contents of an access-method control block. By using MODCB, you don't have to know the format of the control block.

MODCB allows you to tailor access-method control blocks generated with the GENCB macro for specific uses.

The operands of the MODCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. "Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB" gives all the ways of coding each operand for the macros that work at execution.

See "Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros" earlier in this chapter for information on the return codes used to indicate whether the MODCB request was successful.

The format of the MODCB macro used to modify an access-method control block is:

```
[label] MODCB

  ACB= address
  [BSTRNO= number]
  [BUFND= number]
  [BUFNI= number]
  [BUFSP= number]
  [CATALOG=YES | NO]
  [CRA= SCRA | UCRA]
  [DDNAME= ddname]
  [EXLST= address]
  [MACRF=( [ADR] [, CV] [, KEY]
      [CFX | NFX]
      [DDN | DSN]
      [DFR | NDF]
      [DIR | SEQ | SKP]
      [ICI | NCI]
      [IN | OUT]
      [NIS | SIS]
      [NRM | AIX]
      [NRS | RST]
      [NSR | LSR | GSR]
      [NUB | UBF])]
  [MAREA= address]
  [MLEN= number]
  [PASSWD= address]
  [STRNO= number]
```

where:

- `label` is one to eight characters that provides a symbolic address for the MODCB macro.

Control Block Macros 71
ACB=address
specifies the address of the access-method control block to be modified.
The data set identified by the access-method control block must not be
opened. A request to modify the access-method control block of an open
data set will fail.

The remaining operands represent operands of the ACB macro that can be
modified. The value specified replaces the value, if any, presently in the
access-method control block. There are no defaults. See “ACB Macro
(Generate an Access-Method Control Block)” earlier in this chapter for an
explanation of these operands.

If MODCB is used to modify a MACRF option, other options are unaffected,
except when they are inconsistent. For example, if you specify
MACRF=ADR in the MODCB and MACRF=KEY is already indicated in
the control block, both ADR and KEY will now be indicated. But if you
specify MACRF=UBF in the MODCB and NUB is indicated, only UBF will
now be indicated.

If MODCB is used to change the address of an ACB, you must first issue an
ENDREQ macro.

Example: MODCB Macro (Modify an Access-Method Control Block)

In this example, a MODCB macro is used to modify the name
of the exit list in an access-method control block.

MODCB ACB=BLOCK,  
    EXLST=EGRESS

MODCB Macro (Modify an Exit List)

The MODCB macro can be used to modify an exit list.

The operands of the MODCB macro can be expressed as absolute numeric
expressions, as character strings, as codes, as expressions that generate valid
relocatable A-type address constants, in register notation, as S-type address
constants, and as indirect S-type address constants. “Appendix C: Operand
Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways
of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB
Macros” earlier in this chapter for information on the return codes used to
indicate whether the MODCB request was successful.

The format of the MODCB macro used to modify an exit list is:

<table>
<thead>
<tr>
<th>[label]</th>
<th>MODCB</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EXLST=address</td>
</tr>
<tr>
<td></td>
<td>[.EODAD=(address [,A [N][L]])]</td>
</tr>
<tr>
<td></td>
<td>[.JRNAD=(address [,A [N][L]])]</td>
</tr>
<tr>
<td></td>
<td>[.LERAD=(address [,A [N][L]])]</td>
</tr>
<tr>
<td></td>
<td>[.SYNAD=(address [,A [N][L]])]</td>
</tr>
</tbody>
</table>

where:

label
is one to eight characters that provides a symbolic address for the MODCB
macro.
EXLST=address
specifies the address of the exit list to be modified. You can modify an exit list at any time—that is, before or after opening the data set(s) for which the list indicates exit routines. You cannot add an entry to an exit list: if you generate a list without an EODAD exit, for instance, you cannot later modify the list to contain one.

The remaining operands represent operands of the EXLST macro that can be modified or added to an exit list. See “EXLST Macro (Generate an Exit List)” earlier in this chapter for an explanation of these operands.

Example: MODCB Macro (Modify an Exit List)

In this example, a MODCB macro is used to activate an exit in an exit list.

```plaintext
MODCB EXLST=( *, EXLSTADR ),
           EODAD=( EOD, L, A )
```

The MODCB macro's operands are:

- EXLST, which specifies that the address of the exit list to be modified is located at EXLSTADR.
- EODAD, which specifies that the entry for the end-of-data routine is to be marked active in the exit list whose address resides at EXLSTADR. The name of the end-of-data routine, ENDUP, is located at EOD.

MODCB Macro (Modify a Request Parameter List)

The MODCB macro can be used to modify a request parameter list.

The operands of the MODCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter for information on the return codes used to indicate whether the MODCB request was successful. Typical modifications to a request parameter list are to change the indication of length of a record (RECLLEN) when you're processing a data set with variable-length records and to change the type of request (OPTCD), such as from direct to sequential access or from full-key search argument to generic-key search argument.
The format of a MODCB macro used to modify a request parameter list is:

\[
\begin{array}{|c|c|}
\hline
[ \text{label} ] & \text{MODCB} \\
\hline
\text{RPL} = \text{address} \\
\text{ACB} = \text{address} \\
\text{AREA} = \text{address} \\
\text{AREALEN} = \text{number} \\
\text{ARG} = \text{address} \\
\text{ECB} = \text{address} \\
\text{KEYLEN} = \text{number} \\
\text{MSGAREA} = \text{address} \\
\text{MSGLEN} = \text{number} \\
\text{NXTRPL} = \text{address} \\
\text{OPTCD} = ([\text{ADR} | \text{CNV} | \text{KEY}] \\
\quad [\text{DIR} | \text{SEQ} | \text{SKP}] \\
\quad [\text{ARD} | \text{LRD}] \\
\quad [\text{FWD} | \text{BWD}] \\
\quad [\text{ASY} | \text{SYN}] \\
\quad [\text{NSP} | \text{NUP} | \text{UPD}] \\
\quad [\text{KEQ} | \text{KGE}] \\
\quad [\text{FKS} | \text{GEN}] \\
\quad [\text{LOC} | \text{MVE}]) \\
\text{RECLN} = \text{number} \\
\text{TRANSID} = \text{number} \\
\hline
\end{array}
\]

where:

- **label** is one to eight characters that provides a symbolic address for the MODCB macro.
- **RPL address** specifies the address of the request parameter list to be modified. You may not modify an active request parameter list; that is, one that defines a request that has been issued but not completed. To modify such a request parameter list, you must first issue a CHECK or an ENDREQ macro.

The remaining operands represent operands of the RPL macro that can be modified. The value specified replaces the value, if any, presently in the request parameter list. There are no defaults. See “RPL Macro (Generate a Request Parameter List)” earlier in this chapter for an explanation of these operands.

If MODCB is used to modify an OPTCD option within a group of options, the current option for that group is changed, because only one option in a group is effective at a time.

**Example: MODCB Macro (Modify a Request Parameter List)**

In this example, a MODCB macro is used to modify the record-length field in a request parameter list.

```
L 3, length
MODCB RPL=(2), RECLN=3
```

Load the new record length. Register 2 contains the address of the request parameter list. Register 3 contains the record length.
The MODCB macro's operands are:

- **RPL**, which specifies that register 2 contains the address of the request parameter list to be modified.
- **RECLEN**, which specifies that the record-length field is to be modified. The contents of register 3 will replace any current value in the RECLEN field.

**SHOWCB Macro (Display an Access-Method Control Block)**

The SHOWCB macro can be used to cause VSAM to move the contents of various fields in an access-method control block into your work area. You might want to learn the reason for an error or to collect information about a data set in order to alter your program logic or print a message or report as a result of the examination.

The operands of the SHOWCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. "Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB" gives all the ways of coding each operand for the macros that work at execution.

See "Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros" earlier in this chapter for information on the return codes used to indicate whether the SHOWCB request was successful.

The format of the SHOWCB macro used to display fields in an access-method control block is:

```
[ label ]  SHOWCB
          ACB= address
          ,AREA= address
          ,LENGTH= number
          ,[OBJECT=DATA | INDEX]
          ,[FIELDS=([ACBLEN],[AVSPAC],[BFRFND]
                               ,[BSTRNO],[BUFND],[BUFNI]
                               ,[BUFNO],[BUFRES],[BUFSP]
                               ,[CINV],[DDNAME],[ENDRBA]
                               ,[ERROR],[EXLST],[FS]
                               ,[KEYLEN],[LRECL],[MAREA]
                               ,[MLEN],[NCIS],[NDELR],[NEXCP]
                               ,[NEXT],[NINSR],[NIXL],[NLOGR]
                               ,[NRETR],[NSSS],[NUIW]
                               ,[NUPDR],[PASSWD],[RKP]
                               ,[STMST],[STRMAX],[STRNO]
                               ,[UIW])]
```

where:

*label* is one to eight characters that provides a symbolic address for the SHOWCB macro.
**ACB=address**
specifies the address of the access-method control block whose fields are to be displayed. If you used the ACB macro with a label, you can specify the label here. The ACB operand is optional when you wish to display the length of an access-method control block (FIELDS=ACBLEN). (All access-method control blocks have the same length, so you need not specify the address of a particular one.)

**AREA=address**
specifies the address of a work area that you are supplying for VSAM to display the contents of the fields you specify in the FIELDS operand. The contents of the fields are displayed in the order you specify them. The area must begin on a fullword boundary.

**LENGTH=number**
specifies the length, in bytes, of the work area that you are providing for VSAM to display the indicated fields in. See the FIELDS operand for the fields that can be displayed and for the length of each field. If the area is not large enough for all of the fields, VSAM doesn’t display any of their contents and returns an error code indicating it (see “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter).

**OBJECT=DATA | INDEX**
specifies whether fields are to be displayed for the data or for the index.

**FIELDS=(ACBLEN [,AVSPAC][,BFRFND][,BSTRNO][,BUFND][,BUFNI][,BUFNO][,BUFDS][,BUFSP][,CINV][,DDNAME][,ENDRBA][,ERROR][,EXLST][,FS][,KEYLEN][,LRECL][,MAREA][,MLEN][,NCIS][,NDEL][,NEXCP][,NEXT][,NINSR][,NIXL][,NLOGR][,NRETR][,NSSSS][,NUIW][,NUPDR][,PASSWD][,RKP][,STMST][,STRMAX][,STRNO][,UIW])**
specifies the fields whose contents are to be displayed. Some of the fields can be displayed at any time; others only after a data set is opened. The ones that can be displayed only after a data set is opened can, in the case of a key-sequenced data set that has been opened for keyed access, pertain either to the data or to the index. See the OBJECT operand. Figure 8 explains the keywords you can code in the FIELDS operand for an access-method control block.

¹Described in OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications

Figure 8 (Part 2 of 2). FIELDS Operand Keywords for an Access-Method Control Block
Example: SHOWCB Macro (Display an Access-Method Control Block)

In this example, a SHOWCB macro is used to display fields in an access-method control block. The fields displayed (KEYLEN, LRECL, and RKP) permit the program to modify variables to process any one of a number of data sets that have different-sized key fields and records and different placements of key field in a record.

```plaintext
SHOWCB ACB=CONTROL,
      AREA=DISPLAY,
      FIELDS=(KEYLEN,
              LRECL,RKP),
      LENGTH=12
```

```plaintext
DISPLAY DS 0F
KEYLEN DS F
LRECL DS F
RKP DS F
```

The SHOWCB macro's operands are:

- **ACB**, which specifies the address of the access-method control block to be displayed.

- **AREA**, which specifies that the area to be used to display access-method control block fields is to begin on a fullword boundary.

- **FIELDS**, which specifies that the KEYLEN, LRECL, and RKP fields are to be displayed.

- **LENGTH**, which specifies that the length of the area to be used for the display is 12 bytes, enough to accommodate the specified fields.

This display enables the program to set up its variables for the particular data set it has opened.

Example: SHOWCB Macro (Display an Exit List Address)

In this example, a SHOWCB macro is used to get the address of an exit list by displaying the address in an access-method control block that uses the exit list.

```plaintext
SHOWCB ACB=address,
      AREA=address,
      FIELDS=EXLST,
      LENGTH=4
```

The SHOWCB macro's operands are:

- **ACB**, which specifies the address of an access-method control block from which the address of an exit list is to be displayed.

- **AREA** and **LENGTH**, which specify an area and length, four bytes, to be used to display the address of the exit list.

- **FIELDS**, which specifies that the EXLST field in an access-method control block is to be displayed.
SHOWCB Macro (Display an Exit List)

The SHOWCB macro can be used to display fields in an exit list.

The operands of the SHOWCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter for information on the return codes used to indicate whether the SHOWCB request was successful.

The format of the SHOWCB macro used to display fields in an exit list is:

```
[label] SHOWCB [EXLST=address, ]
AREA=address
,LENGTH=number
,FIELDS=(EODAD,EXLLEN,JRNAD)
       ,[LERAD,SYNAD])
```

where:

- **label**
  is one to eight characters that provides a symbolic address for the SHOWCB macro.

- **AREA=address**
  specifies the address of a work area that you are supplying for VSAM to display the contents of the fields you specify in the FIELDS operand. The contents of the fields are displayed in the order you specify them. The area must begin on a fullword boundary.

- **LENGTH=number**
  specifies the length, in bytes, of the work area that you are providing for VSAM to display the indicated fields in. Each exit-list field requires a fullword. If the area is not large enough for all of the fields, VSAM doesn’t display any of their contents and returns an error code indicating it (see “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter).

- **[EXLST=address]**
  specifies the address of the exit list whose fields are to be displayed. If you used the EXLST macro with a label, you can specify the label here. The EXLST operand is optional only when you wish to display the length that an exit list can have (see FIELDS=EXLLEN below).

- **FIELDS=(EODAD,EXLLEN,JRNAD)**
  specifies the values to be displayed, as follows:

  - **EODAD**
    specifies that the address of the end-of-data-set routine is to be displayed.

  - **EXLLEN**
    specifies that the length of the exit list indicated in the EXLST operand or if EXLST is omitted, the maximum length an exit length can have, is to be displayed.
JR NAD
specifies that the address of the journaling routine is to be displayed.

LERAD
specifies that the address of the logical-error analysis routine is to be displayed.

SYNAD
specifies that the address of the physical-error analysis routine is to be displayed.

You can use SHOWCB to display the address of an exit routine only if the exit routine is indicated in the exit list. If it isn’t, the SHOWCB request will fail. Use TESTCB to test whether an entry for a given exit type is present in the exit list and to find out whether the exit is active and whether the routine is to be loaded.

Example: SHOWCB Macro (Display the Length of an Exit List)

In this example, a SHOWCB macro is used to display the maximum length of an exit list. The maximum length of an exit list is subsequently used in a GENCB macro to get virtual storage for an exit list.

```
SHOWCB AREA=LENGTH,
       FIELDS=EXLEN,
       LENGTH=4

L    0,LENGTH
    GETMAIN R, LV=(0)
    LR    2, 1
    GENCB BLK=EXLST,
           LENGTH=(*,LENGTH),
           WAREA=(2)
```

The SHOWCB macro’s operands are:

- **AREA** and **LENGTH**, which specify the area, which begins on a fullword boundary, and its length, four bytes, that is to be used for the display.
- **FIELDS**, which specifies that the maximum length of an exit list is to be displayed. Because only EXLEN is specified, the EXLST operand is omitted.

The GENCB macro specifies a work area in which an exit list is to be generated. The length of the work area is located at LENGTH, where the maximum length of an exit list was put as a result of the SHOWCB macro.
SHOWCB Macro (Display a Request Parameter List)

The SHOWCB macro can be used to display fields in a request parameter list.

The operands of the SHOWCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution. See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter for information on the return codes used to indicate whether the SHOWCB request was successful.

The format of the SHOWCB macro used to display fields in a request parameter list is:

```
[label] SHOWCB RPL= address
\,AREA= address
\,LENGTH= number
\,FIELDS=[(ACB\[,AIXPC\[,AREA\[,AREALEN\]
\,[ARG\[,ECB\[,FDBK\[,FTNCD\]
\,[KEYLEN\[,MSGAREA\[,MSGLEN
\,[NXTRPL\[,RBA\[,RCLLEN
\,[RPLLEN\[,TRANSID\])
```

where:

- **label** is one to eight characters that provides a symbolic address for the SHOWCB macro.

- **AREA=address** specifies the address of a work area that you are supplying for VSAM to display the contents of the fields you specify in the FIELDS operand. The contents of the fields are displayed in the order you specify them. The area must begin on a fullword boundary.

- **LENGTH=number** specifies the length, in bytes, of the work area that you are providing for VSAM to display the indicated fields in. Each request parameter list field requires a fullword. If the area is not large enough for all of the fields, VSAM doesn’t display any of their contents and returns an error code indicating it (see “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter).

- **RPL=address** specifies the address of the request parameter list whose fields are to be displayed. If you used the RPL macro with a label, you can specify the label here. The RPL operand is optional when you wish to display the length of a request parameter list (FIELDS=RPLLEN). (All VSAM request parameter lists have the same length, so you need not specify the address of a particular one.)
FIELD$ = (\{\text{ACB}\}, \{\text{AIXPC}\}, \{\text{AREA}\}, \{\text{AREALEN}\}, \{\text{ARG}\}, \{\text{ECB}\}, \{\text{FDBK}\}, \{\text{FTNCD}\}, \{\text{KEYLEN}\}, \{\text{MSGAREA}\}, \{\text{MSGLEN}\}, \{\text{NXTRPL}\}, \{\text{RBA}\}, \{\text{RECLen}\}, \{\text{RPLLEN}\}, \{\text{TRANSID}\})$

specifies the fields whose contents are to be displayed. Figure 9 explains the keywords you can code in the FIELDS operand for a request parameter list.

<table>

Figure 9. FIELDS Operand Keywords for a Request Parameter List

Control Block Macros 83
Example: SHOWCB Macro (Display a Physical-Error Message)

In this example, a SHOWCB macro is used to display a physical-error message. This example assumes that there is no SYNAD routine (or the SYNAD exit is inactive), in which case, VSAM returns control to your program following the last executable instruction if a physical error occurs. Register 15 indicates a physical error (12), and the feedback field in the request parameter list contains a code identifying the error; the message area contains more details about the error. Register 1 points to the request parameter list.

```
REQUEST RPL MSGAREA=
    MESSAGES,
    MSGLEN=128
```

```
  ...
  ...
SHOWCB AREA(MSGADDR),
    FIELDS(MSGAREA),
    LENGTH=4,
    RPL(REQUEST)
LTR 15, 15
BNZ CHECK0
  ...
  ...
CHECK0...
```

Display failed.

```
MESSAGES DS CL128
For VSAM to give you a detailed message about a physical error.
MSGADDR DS F
For displaying the address of the message area with SHOWCB.
```

The RPL macro in this example provides for a message area, MESSAGES, of 128 bytes to be used for any physical-error message.

The SHOWCB macro’s operands are:

- **AREA** and **LENGTH**, which specify a four-byte area, MSGADDR, to be used for displaying the address of the message area for the associated request parameter list.
- **FIELDS**, which specifies that the address of the message area is to be displayed.
- **RPL**, which specifies the name, REQUEST, of the request parameter list for which the message-area address is to be displayed.
TESTCB Macro (Test an Access-Method Control Block)

With the TESTCB macro, you can cause VSAM to set the condition code in the PSW (program status word) as a result of a comparison between the contents of a field that you specify and a value that you specify. Only one keyword can be specified each time TESTCB is issued. You might want to do this to:

- Find out whether an action (for example, opening a data set or activating an exit) has been done by VSAM or your program
- Find out what kind of a data set is being processed in order to alter your program logic as a result of the test.

You examine the PSW condition code after issuing a TESTCB macro (and examining the return code in register 15). For keywords specified as an option or a name, you test for an equal or unequal comparison; for keywords specified as an address or a number, you test for an equal, unequal, high, low, not-high, or not-low condition.

VSAM compares A to B, where A is the contents of the field and B is the value to which it is to be compared. A low condition means, for example, that A is lower than B—that is, that the value in the control block is lower than the value you specified. You may specify only one keyword to be tested.

These keywords are the same as those that can be specified in the SHOWCB macro to display fields in an ACB. Fields can be tested at the same time they are displayed. If you specify a list of option codes for a keyword (for example, MACRF=(ADR,DIR)), each of them must equal the corresponding value in the control block for you to get an equal condition.

Some of the fields can be tested at any time; others only after a data set is opened. The ones that can be tested only after a data set is opened can, in the case of a key-sequence data set, pertain either to the data or to the index. See the OBJECT operand.

The operands of the TESTCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” earlier in this chapter for information on the return codes used to indicate whether the TESTCB request was successful.
Only one keyword can be specified each time you issue the macro. The format of the TESTCB macro used to test a field in an access-method control block is:

```
[ label ] TESTCB

</tbody>
</table>
```

where:

**ACB=address**
specifies the address of the access-method control block whose information you want to test. You may omit it only if you're testing the length of an access-method control block (ACBLEN=number). (All VSAM access-method control blocks have the same length.)

**ERET=address**
specifies the address of a routine that VSAM is to give control if, because of an error, it is unable to test for the condition you specify. For example, testing AVSPAC in an access-method control block for an unopened data set would fail. VSAM indicates in register 15 whether it could do the test and, if not, indicates in register 0 the reason it couldn't. (The reasons are discussed earlier in this chapter under “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros.”) A failure trying to execute TESTCB indicates a basic logical problem in the processing program, so the error routine would probably issue an ABEND. If it lets the program continue, it must branch to the continuation point itself—and not return to VSAM.

**OBJECT={DATA | INDEX}**
specifies whether you want to test a field for data or for index.

**ATRB=(ESDS|KSDS|REPL|RRDS|SPAN|SSWD|UNQ|WCK)**
specifies, for an open data set, the attribute that is to be tested for, as follows:

- **ESDS**
  entry-sequenced data set

- **KSDS**
  key-sequenced data set

- **REPL**
  some portion of the index is replicated

- **RRDS**
  relative record data set

- **SPAN**
  data set contains spanned records

- **SSWD**
  sequence set is adjacent to the data

- **UNQ**
  unique keys

- **WCK**
  write operations for the data set are being verified

**CATALOG=YES|NO**
specifies that a test is to be made to determine, anytime, whether or not the access-method control block specifies a catalog data set.

**CRA=SCRA|UCRA**
specifies that a test is to be made to determine, anytime, whether catalog recovery area control blocks are to be built in system storage or user storage.
specifies that a test is to be made to determine, anytime, what option or combination of options is being used for processing.

**OFLAGS=OPEN**

specifies that a test is to be made to determine, after open, whether the data set identified by the control block has been opened.

**OPENOBJ=PATH | BASE | AIX**

specifies that a test is to be made to determine, after open, whether an opened object is a path, a base cluster, or an alternate index.

The remaining operands represent fields in an access-method control block that can be compared with the value specified. These fields are the same as those that can be displayed by using the SHOWCB macro. See Figure 8 for an explanation of these fields.

If you omit a routine to handle error conditions, you can examine register 15 following TESTCB by using a branch table, for example, but don't alter the PSW condition code that VSAM set to indicate the result of a test until you've had a chance to test it.

**Example: TESTCB Macro (Use an ERET Routine)**

In this example, a TESTCB macro is used to determine whether the data set defined by the access-method control block CLOPEN has been opened. An ERET routine, which gets control automatically when a test is unsuccessful, is provided.

```
TESTCB ACB=CLOPEN,
       ERET=ERROR,
       OFLAGS=OPEN

BNE    UNOPEN
OPEN   ...
UNOPEN ...
ERROR  ...
```

Is the data set open?

Go to routine for an unopen data set.

Answer to test question was yes.

Answer to test question was no.

An ERET routine to analyze any failure of VSAM to carry out the test—same routine could serve other TESTCBs.
Example: TESTCB Macro (Test for Data-Set Attributes)

In this example, a TESTCB macro is used to determine whether a data set is a key-sequenced or an entry-sequenced data set.

```
LIST RPL
.
.
SHOWCB AREA=DATAFACT,
    FIELDS=ACB,
    LENGTH=4,
    RPL=LIST
LTR 15,15
BNZ CHECK0
TESTCB ACB=(*,
    DATAFACT),
    ATRB=KSDS,
    ERET=CHECK0
BE KEYSEQ
.
.
.
KEYSEQ ...
CHECK0 ...
.
.
DATAFACT DS F
```

Is the data set key-sequenced?

Yes.

Data set is key sequenced.

Display or test failed.

For displaying address of access-method control block.

The SHOWCB macro's operands are:

- AREA and LENGTH, which specify a four-byte area, DATAFACT, aligned on a fullword boundary, to be used for the display.
- FIELDS and RPL, which specify that the address of the access-method control block in the LIST request parameter list is to be displayed.

The TESTCB macro's operands are:

- ACB, which specifies that a field in the access-method control block, the address of which is located at DATAFACT, is to be tested. The SHOWCB macro put the address of the access-method control block at DATAFACT.
- ATRB, which specifies that the access-method control block is to be tested to determine whether it is a key-sequenced data set.
- ERET, which specifies that a routine named CHECK0 is to be given control if an error occurs that makes it impossible to make the test.

There is no need to examine the feedback field in an EODAD routine because it can be assumed to contain the end-of-data-set indication.
TESTCB Macro (Test an Exit List)

The TESTCB macro can be used to test fields in an exit list.

The operands of the TESTCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution.

The format of the TESTCB macro used to test fields in an exit list is:

| [label] | TESTCB | EXLST = address 
| [ ,ERET = address ] 
| ,EODAD = [0 | ([address ][,A | N][,L]) ] 
| JRNAD = [0 | ([address ][,A | N][,L]) ] 
| LERAD = [0 | ([address ][,A | N][,L]) ] 
| SYNAD = [0 | ([address ][,A | N][,L]) ] 
| [ ,EXLLEN = number ] |

where:

label
is one to eight characters that provides a symbolic address for the TESTCB macro.

EXLST = address
specifies the address of the exit list whose information you want to test. You may omit it only if you’re testing the maximum length of an exit list (EXLLEN = number).

ERET = address
specifies the address of a routine that VSAM is to give control if, because of an error, it is unable to test for the condition you specify. For example, testing AVSPAC in an access-method control block for an unopened data set would fail. VSAM indicates in register 15 whether it could do the test and, if not, indicates in register 0 the reason it couldn’t. (The reasons are discussed earlier in this chapter under “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros.”) A failure trying to execute TESTCB indicates a basic logical problem in the processing program, so the error routine would probably issue an ABEND. If it lets the program continue, it must branch to the continuation point itself—and not return to VSAM.

EODAD = [0 | ([address ][,A | N][,L]) ] 
JRNAD = [0 | ([address ][,A | N][,L]) ] 
LERAD = [0 | ([address ][,A | N][,L]) ] 
SYNAD = [0 | ([address ][,A | N][,L]) ]

specifies the exit about which you are asking a yes-no question. If you code more than one operand for an exitname, each of them must equal the corresponding value in the control block for you to get an equal condition. The values that can be tested are:

0
specifies that a test is to be made to determine whether an entry is provided for the exit in the exit list.
address
specifies that a test is to be made to determine whether this is the
address of the exit. Tests for an address result in an equal, unequal,
high, low, not-high, or not-low condition. Tests for a combination of an
address and A, N, or L result in an equal or unequal condition.

A | N
specifies that a test is to be made to determine whether an exit is active
(A) or not active (N). Tests for A or N result in an equal or unequal
condition.

L
specifies that a test is to be made to determine whether the address is
the location of an 8-byte field containing the name of a module to be
loaded rather than the entry point of the routine. Tests for L result in an
equal or unequal condition.

EXLEN=number
specifies either the maximum length that an exit list can have (if you don’t
code the EXLST operand) or the actual length of the exit list indicated by
the EXLST operand. If you specify an exit, you may not also specify
EXLEN; if you specify EXLEN, you may not also specify an exit.

If you omit a routine to handle error conditions, you can examine register 15
following TESTCB by using a branch table, for example, but don’t alter the
PSW condition code that VSAM set to indicate the result of a test until
you’ve had a chance to test it.

Example: TESTCB Macro (Use a Branch Table)

In this example, a TESTCB macro is used to test whether ENDPROC is the
routine supplied for the EODAD exit in the exit list EXITS, and whether the
EODAD exit is active. A branch table is used to determine whether the test is
successful.

TESTCB EODAD=(ENDPROC,
A), EXLST=EXITS
B *+4(15)

If the test was made successfully, register 15
contains 0 and the next instruction is executed.

B TEST1

If it was unsuccessful, register 15 contains 4 and
the next instruction is executed.

ABEND 2, DUMP
TEST1 BNE NO
YES ...
NO ...

Yes, ENDPROC is supplied and active.
ENDPROC isn’t supplied, or the exit isn’t active.
The TESTCB macro can be used to test fields in a request parameter list.

The operands of the TESTCB macro can be expressed as absolute numeric expressions, as character strings, as codes, as expressions that generate valid relocatable A-type address constants, in register notation, as S-type address constants, and as indirect S-type address constants. “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” gives all the ways of coding each operand for the macros that work at execution.

See “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros” for information on the return codes used to indicate whether the TESTCB request was successful earlier in this chapter.

The format of the TESTCB macro to test fields in a request parameter list is:

```
[ label ] TESTCB

RPL= address
[,ERET= address ]
{ADXFLAG=AIXPKP |
AIXPC= number |
FTNCD= number |
I/O=COMPLETE |
OPTCD= ([ADR][,ARD][,ASY][,BWD]
[,CNV][,DIR][,FKS][,FWD]
[,GEN][,KEQ][,KEY][,KGE][,LOC]
[,LRD][,MVE][,NSP][,NUP][,SEQ]
[,SKP][,SYN][,UPD]) |
ACB= address |
AREA= address |
AREALEN= number |
ARG= address |
ECB= address |
FDBK= number |
KEYLEN= number |
MSGAREA= address |
MSGLEN= number |
NXTRPL= address |
RBA= number |
RECLEN= number |
RPLLEN= number |
TRANSID= number }
```

where:

- **label** is one to eight characters that provides a symbolic address for the TESTCB macro.
- **RPL=address** specifies the address of the request parameter list whose information you want to test. You may omit it only if you're testing the length of a request parameter list (RPLLEN=number). (All request parameter lists have the same length.)
ERET=<address>

specifies the address of a routine that VSAM is to give control if, because of an error, it is unable to test for the condition you specify. For example, testing AVSPAC in an access-method control block for an unopened data set would fail. VSAM indicates in register 15 whether it could do the test and, if not, indicates in register 0 the reason it couldn’t. (The reasons are discussed earlier in this chapter under “Return Codes from the GENCB, MODCB, SHOWCB, and TESTCB Macros.”) A failure trying to execute TESTCB indicates a basic logical problem in the processing program, so the error routine would probably issue an ABEND. If it lets the program continue, it must branch to the continuation point itself—and not return to VSAM.

AIXFLAG=AIXPKP

specifies that prime-key pointers are used rather than RBAs.

AIXPC=number

specifies the pointer count.

FTNCD=number

specifies whether the upgrade set is correct or may have been modified by a request. These codes are described under “Function Codes” in the chapter “Request Macros.”

IO=COMPLETE

specifies that a test is to be made to determine whether an asynchronous request has been completed. (When you issue a CHECK macro, you suspend processing until a request has been completed if it hasn’t yet been completed.)

OPTCD=(ADR[,ARD][,ASY][,BWD][,CNV][,DIR][,FKS][,FWD]
     [,GEN][,KEQ][,KEY][,KGE][,LOC][,LRD][,MVE][,NSP]
     [,NUP][,SEQ][,SKP][,SYN][,UPD])

specifies that a test is to be made to determine what option or combination of options is being used for the request.

The remaining operands specify fields in a request parameter list and values; the contents of a field are to be compared to the specified value. These fields are the same as those that can be displayed by using a SHOWCB macro. See Figure 9 under “SHOWCB Macro (Display a Request Parameter List)” for an explanation of these fields. Fields can be tested at the same time they are displayed.

You may specify only one keyword. If you code a list of option codes (for example, OPTCD=(KEY,DIR)), each of them must equal the corresponding value in the control block for you to get an equal condition.

If you omit a routine to handle error conditions, you can examine register 15 following TESTCB by using a branch table, for example, but don’t alter the PSW condition code that VSAM set to indicate the result of a test until you’ve had a chance to test it. Examples of using an ERET routine and using a branch table are given at the end of the section.
Example: TESTCB Macro (Test a Request Parameter List)

```
TESTCB RPL=(3),
    RECLEN=80
    BE      NOCHNGE
CHANGE    ...
    BE      NOCHNGE
```

Because the record length in the request parameter list was not 80, the length indicator must be modified so that it is 80.

Because the record length in the request parameter list was 80, no change is required.

The TESTCB macro's operands are:

- `RPL`, which specifies that the address of the request parameter list to be tested is contained in register 3.

- `RECLEN`, which specifies that the record length indicated in the request parameter list is to be tested to determine whether it is 80.
REQUEST MACROS

This chapter describes the macro instructions that cause some action to be taken regarding data or processing. The request macros are:

- **GET**, which causes a record to be retrieved.
- **PUT**, which causes a record to be stored.
- **ERASE**, which causes a record previously retrieved for update to be deleted from a key-sequenced data set.
- **POINT**, which causes VSAM to position at the desired record.
- **CHECK**, which causes processing to be suspended to await the completion of some event.
- **ENDREQ**, which causes a specified request to be terminated.

GETIX and PUTIX, which cause an index record to be retrieved and stored, are described in *OS/VS Virtual Storage Access Method (VSAM) Options for Advanced Applications*.

Each request macro makes use of a request parameter list; the request parameter list defines the action to be taken. For example, when a GET macro points to a request parameter list that specifies synchronous, sequential retrieval, the next record in sequence is retrieved. When an ENDREQ macro points to a request parameter list, any current request (for example, a PUT) for that request parameter list is ended immediately.

A return code in register 15 and a code in the feedback field of the request parameter list indicate what happened as a result of a request macro. The return codes in register 15, feedback-field codes, and the request macros are described below.

### Return Codes from Request Macros

After you issue a request macro for access to data or a CHECK or ENDREQ macro, register 15 contains a return code. The meaning of the return code depends on whether processing is asynchronous or synchronous.

After you issue an asynchronous request for access to a data set, VSAM indicates in register 15 whether the request was accepted, as follows:

<table>
<thead>
<tr>
<th>Reg. 15</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request was accepted.</td>
</tr>
<tr>
<td>4</td>
<td>Request was not accepted because the request parameter list indicated by the request (RPL-address) was active for another request.</td>
</tr>
</tbody>
</table>

If the asynchronous request was accepted, you issue a CHECK after doing your other processing so VSAM can indicate in register 15 whether the request was completed successfully, set a return code in the feedback field, and exit to any appropriate exit routine. If the request was not accepted, you should either wait until the other request is complete (for example, by issuing a CHECK on the request parameter list) or terminate the other request (using ENDREQ). Then you can reissue the rejected request.
After a synchronous request, or a CHECK or ENDREQ macro, register 15 indicates whether the request was completed successfully, as follows:

<table>
<thead>
<tr>
<th>Reg. 15</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>4</td>
<td>Request was not accepted because the request parameter list indicated by the request (RPL-address) was active for another request.</td>
</tr>
<tr>
<td>8</td>
<td>Logical error; specific error is indicated in the feedback field in the RPL.</td>
</tr>
<tr>
<td>12</td>
<td>Physical error; specific error is indicated in the feedback field in the RPL.</td>
</tr>
</tbody>
</table>

**Feedback-Field Codes**

Paired with the 0, 8, and 12 indicators in register 15 are codes in the feedback field of the request parameter list. The feedback codes for the 0, or successful, indicator in register 15, which doesn't cause VSAM to exit to an exit routine, are:

<table>
<thead>
<tr>
<th>FDBK</th>
<th>Code</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Request completed successfully. For retrieval, VSAM mounted another volume to locate the record; for storage, VSAM allocated additional space or mounted another volume.</td>
</tr>
<tr>
<td>8</td>
<td>8</td>
<td>Duplicate key follows.</td>
</tr>
<tr>
<td>12</td>
<td>12</td>
<td>Write-buffer suggested (shared resources only).</td>
</tr>
</tbody>
</table>

You can examine the feedback field of the request parameter list with the SHOWCB or TESTCB macro. You may code your examination routine immediately following the request macro. However, logical errors, physical errors, and reaching the end of the data set all cause VSAM to exit to the appropriate exit routine, if you provide it.

Coordinate error checking in your program with your error-analysis exit routines. If they terminate the program, for instance, you would not need to code a check for an error after a request. But if a routine returns to VSAM to continue processing, you might check register 15 after a request to determine whether there was an error. Even though the error was handled by an exit routine, you may want to modify processing in light of the error.
Function Codes

When a logical or physical error occurs, VSAM provides a code that identifies the function being attempted when the error occurred and indicates whether the alternate-index upgrade set is correct following the request that failed. The function code can be displayed and tested by the SHOWCB and TESTCB macros. The codes and their meanings are:

<table>
<thead>
<tr>
<th>Code</th>
<th>Function</th>
<th>Upgrade Set Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00'</td>
<td>An attempt to access the base cluster</td>
<td>Correct</td>
</tr>
<tr>
<td>X'01'</td>
<td>An attempt to access the base cluster</td>
<td>May be incorrect</td>
</tr>
<tr>
<td>X'02'</td>
<td>An attempt to access the alternate index over a base cluster</td>
<td>Correct</td>
</tr>
<tr>
<td>X'03'</td>
<td>An attempt to access the alternate index over a base cluster</td>
<td>May be incorrect</td>
</tr>
<tr>
<td>X'04'</td>
<td>Upgrade processing</td>
<td>Correct</td>
</tr>
<tr>
<td>X'05'</td>
<td>Upgrade processing</td>
<td>May be incorrect</td>
</tr>
</tbody>
</table>

Logical Errors

If a logical error occurs and you have no LERAD routine (or the LERAD exit is inactive), VSAM returns control to your program following the last executed instruction. Register 15 indicates a logical error (8), and the feedback field in the request parameter list contains a code identifying the error. Register 1 points to the request parameter list. Figure 10 gives the logical-error return codes in the feedback field and explains what each one means.
<table>
<thead>
<tr>
<th>Code</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>End of data set encountered (during sequential or skip-sequential retrieval), or the search argument is greater than the high key of the data set. Either no EODAD routine is provided, or one is provided and it returned to VSAM and the processing program issued another GET.</td>
</tr>

Figure 10 (Part 2 of 2). Logical-Error Return Codes in Feedback Field
Physical Errors

If a physical error occurs and you have no SYNAD routine (or the SYNAD exit is inactive), VSAM returns control to your program following the last executable instruction. Register 15 indicates a physical error (12), and the feedback field in the request parameter list contains a code identifying the error; the message area contains more details about the error. Register 1 points to the request parameter list. Figure 11 gives the physical-error return codes in the feedback field and explains what each one indicates.

- "DATA CHECK"
- "OVER RUN"
- "TRACK COND CK"
- "SEEK CHECK"
- "COUNT DATA CHK"
- "TRACK OVERRUN"
- "CYLINDER END"
- "INVALID SEQ"
- "NO RECORD FOUND"
- "FILE PROTECT"
- "MISSING A.M."
- "OVERFL INCP"

Figure 12 (Part 2 of 3). Physical-Error Message Format
GET Macro (Retrieve a Record)

The GET macro is used to retrieve a record.

The GET macro is used with the PUT macro to update records. See "PUT Macro (Store a Record)" later in this chapter for examples that show the use of the GET macro to update records. The GET macro is used with the ERASE macro to delete records in a key-sequenced or relative record data set. See "ERASE Macro (Delete a Record)" later in this chapter for examples that show the use of the GET macro to delete records.

The format of the GET macro is:

```
[label]   GET   RPL= address
```

where:

- `label` is one to eight characters that provides a symbolic address for the GET macro.

- `RPL= address` specifies the address of the request parameter list that defines this GET request. You may specify the address in register notation (using a register from 1 through 12, enclosed in parentheses) or specify it with an expression that generates a valid relocatable A-type address constant.
Example: Keyed-Sequential Retrieval

In this example, a GET macro is used to sequentially retrieve records by key. Fixed-length, 100-byte records are moved to a work area. Processing is synchronous.

```
INPUT
ACB
MACRF=(KEY, SEQ, IN)
```

```
RETRVE
RPL
MACRF=(KEY, SEQ, IN)
AREA=IN
AREALEN=100
OPTCD=(KEY, SEQ, SYN, NUP, MVE)
```

```
RPL=RETRVE
15,15
```

```
ERROR
BNZ ERROR
BNZ
B
```

```
IN
DS
CL100
```

All MACRF and OPTCD options specified are defaults and could have been omitted.

This GET or identical GETs can be issued, with no change in the request parameter list, to retrieve subsequent records in key sequence.

The records are retrieved in key sequence. No search argument has to be specified; VSAM is positioned at the first record in key sequence when the data set is opened, and the next record is retrieved automatically as each GET is issued. The branch to ERROR could also be taken if the end of the data set is reached.

Example: Skip-Sequential Retrieval

In this example, a GET macro is used to retrieve variable-length records synchronously. Records are to be processed in the I/O buffer. The search argument is full key, compared greater-than-or-equal; key length is eight bytes.

The records are retrieved in key sequence, but some records are skipped. Skip-sequential retrieval is very similar to keyed-direct retrieval, except that you must retrieve records in ascending sequence (with skips) rather than in a random sequence.

```
GENCB
BLK=ACB,
DDNAME=INPUT,
MACRF=(KEY, SKP, IN)
```

```
LTR 15,15
BNZ CHECK0
LR 2,1
```

VSAM gets an area in virtual storage to generate the access-method control block and returns the address in register 1.

IN contains a data record after GET is completed.

Request wasn't accepted or failed.
The macros and instructions are described, as follows:

- The first GENCB generates an access-method control block, which specifies keyed, skip-sequential, and input processing. The address of the access-method control block is stored in register 2.

- The second GENCB generates a request parameter list. The address of the request parameter list is stored in register 3.

- MVC moves the search argument into SRCHKEY, the area defined for the search argument.

- GET specifies that the record pointed at by the request parameter list whose address is in register 3 is to be retrieved. Records are retrieved by a skip-sequential search through the sequence set of the index.
Example: Addressed-Sequential Retrieval

In this example, one GET macro is used to retrieve multiple fixed-length, 20-byte records. The records are moved to a work area (only option).

```

Number of lists (10).
Address of the first list.
Length of all of the lists. Registers 0 and 1 contain length and address of the generated control blocks when VSAM returns control after GENCB.
Prepare for following division.
Divide number of lists into length of all of the lists.
Save the resulting length of a single list for an offset.
Save address of the first list.
Address of the first work area.
Do the following six instructions ten times to set up all of the request parameters lists. The tenth time, register 4 must be set to 0 to indicate the last request parameter list in the chain.
Address the next list.
In each request parameter list, indicate the address of the next list and the address and length of the work area.
Address the next list.
Address the next work area.
Restore register 2 to address the first list before continuing to process.
Process the ten records that have been retrieved by the GET.
CHECK0 ...

ERROR ...

RECAREA DS CL200

Display the feedback field (FIELDS=FDBK) of each request parameter list to find out which one had an error.

Space for a work area for each of the ten request parameter lists.

The GENCB macro generates ten request parameter lists; the lists are subsequently chained together by using the MODCB macro to modify the NXTRPL operand in each copy. Because SEQ is specified in each request parameter list and no previous request has been issued against the access-method control block since it was opened, retrieval begins at the beginning of the data set. Each time the GET macro is executed, VSAM is positioned at the next record in RBA sequence. VSAM moves each record into the work area provided for the request parameter list that identifies the record.

If an error occurred for one of the request parameter lists in the chain and you have supplied error-analysis routines, VSAM takes a LERAD or SYNAD exit before returning to your program. Register 15 is set to indicate the status of the request. A code of 0 indicates that no error was associated with any of the request parameter lists. Any other code indicates that an error occurred for one of the request parameter lists. You should issue a SHOWCB macro for each request parameter list in the chain to find out which one had an error. VSAM doesn’t process any of the request parameter lists beyond the one with an error.
Example: Keyed-Direct Retrieval

In this example, a GET macro is used to retrieve fixed-length, 100-byte records directly by key. The key length is 15 bytes; the search argument is a five-byte generic key, compared equal. The control blocks are generated at assembly.

```
INPUT ACB MACRF=(KEY, DIR, IN)
RETRVE RPL ACB=INPUT, AREA=IN, AREALEN=4,
OPTCD=(KEY,DIR, SYN,NUP,KEQ,GEN, LOC),
ARG=KEYAREA, KEYLEN=5
.
.
.
LOOp MvC KEYAREA,source
GET RPL=RETRVE
LTr 15,15
Bnz ERROR
.
.
.
B LOOP
ERROR...
.
.
.
IN DS CL4
KEYAREA DS CL5
```

You specify all parameters for the request in the RPL macro.

Search argument for retrieval, moved in from a table or a transaction record.

This GET or identical GETs can be issued with no change in the RPL: just specify each new search argument in the field KEYAREA.

Process the record.

Request wasn't accepted or failed.

VSAM puts here the address of the record within the I/O buffer.

You specify the search argument here.

The generic key specifies a class of records. For example, if you search on the first third of employee number, VSAM positions at and retrieves the first of presumably several records that start with the specified characters. To retrieve all of the records in that class, either switch to sequential access or to a full-key search with greater-than-or-equal comparison.
Example: Addressed-Direct Retrieval

In this example, a GET macro is used to retrieve fixed-length, 20-byte records. The records are to be moved to a work area.

</tbody>
</table>

You specify the RBA search argument here for each request.

The RBA provided for a search argument must match the RBA of a record. Keyed insertion and deletion of records in a key-sequenced data set will probably cause the RBAs of some records to change. Therefore, if you process a key-sequenced data set by addressed-direct access (or by addressed-sequential access using POINT), you need to keep track of changes. You can use the JRNAD exit for this purpose. See “EXLST Macro (Generate an Exit List)” in the chapter “Control Block Macros.”
Example: Switch from Direct to Sequential Retrieval

In this example, GET macros are used to retrieve fixed-length, 100-byte records. The control blocks were generated at assembly, but the MODCB macro is used to modify the request parameter list to permit switching from keyed-direct to keyed-sequential retrieval. For the direct request preceding sequential requests, the search argument is an eight-byte, generic key, compared equal. Positioning is requested for direct requests.

```
| INPUT | ACB   | MACRF= (KEY,DIR,SEQ,IN)   | Both direct and sequential access specified. |
| RETRVE RPL  | ACB=INPUT,AREA=IN,AREALEN=100,OPTCD=(KEY,DIR,SYN,NSP,KEQ,GEN,MVE),ARG=KEYAREA,KEYLEN=8 |
|          |       |                           | NSP specifies that VSAM is to remember its position. |
| LOOP MVC   | KEYAREA,source | Search argument for direct retrieval, moved in from a table or a transaction record. |

Request Macros 109
Modification failed.

VSAM puts retrieved records here.

Specify the generic key for a direct request here.

Positioning is associated with a request parameter list; the MODCB macro is used to modify a single request parameter list that alternately defines requests for both types of access rather than use a different request parameter list for each type.

With direct retrieval, VSAM doesn’t remember its position for subsequent sequential retrieval unless you explicitly request it (OPTCD:NSP or UPD). After a direct GET for update, VSAM is positioned for a subsequent PUT, ERASE, or sequential GET. If you modify OPTCD=(DIR,NUP) to OPTCD=SEQ, you must issue POINT to get VSAM positioned for sequential retrieval, as NUP indicates that no positioning is desired with a direct GET.

If you have chained many request parameter lists together, one position is remembered for the whole chain. For example, if you issue a GET that gives the address of the first request parameter list in the chain, the position of VSAM when the GET request is complete is at the record following the record defined by the last request parameter list in the chain. Therefore, modifying OPTCD=(DIR,NSP) in each request parameter list in a chain to OPTCD=SEQ implies continuing with sequential access relative to the last of the direct request parameter lists.

**PUT Macro (Store a Record)**

The PUT macro is used to store a record.

The format of the PUT macro is:

```
[ label ] PUT RPL= address
```

where:

- **label**
  - is one to eight characters that provides a symbolic address for the PUT macro.

- **RPL= address**
  - specifies the address of the request parameter list that defines the request. You may specify the address in register notation (using a register from 1 through 12, enclosed in parentheses) or specify it with an expression that generates a valid relocatable A-type address constant.

**Note:** If the PUT macro is being used to load records into an empty data set, the STRNO value in the access-method control block must be 1.
Example: Keyed-Sequential Insertion

In this example, a PUT macro is used to perform keyed-sequential insertion. Variable-length records with a key length of 15 bytes are to be moved from a work area. Some records will be inserted between existing records; other records will be added at the end of the data set.

```
BLOCK ACB DDNAME=OUTPUT,

       ERROR ...

       Work area for building records.

       Work area for building records.

The request parameter list, LIST, is associated with the access-method control block, BLOCK. The length of each record to be inserted is put into register 2, which is subsequently used by MODCB to change the record length in the request parameter list. The record length is, therefore, correctly indicated in the request parameter list before the PUT macro is issued. The execution of the PUT macro causes VSAM to skip ahead (never back) to the next record.
Example: Record RBAs When Loading

In this example, a PUT macro is used to record the RBAs of records as they are loaded into a key-sequenced data set. The RBAs are recorded in a table with 20-byte entries (4 bytes for RBA, 15 bytes for associated key, and 1 byte of padding so the next entry begins on a fullword boundary).

```
LA 3,RBATABLE          Address the beginning of the table.
.
.
LOOP L 2,source       Put length of record to be inserted into register 2.

RBA    DS CL4
KEY    DS CL15
      DS CL1
```

Padding to keep each RBA entry on a fullword boundary: SHOWCB's display area must be on a fullword boundary.

The need to process a key-sequenced data set by address should be unusual, but by recording the RBA of each record in a key-sequenced data set, you have search arguments for possible processing of the data set by addressed-direct retrieval and by addressed-sequential retrieval using the POINT macro. (You don't need to know RBAs to process a key-sequenced data set by simple addressed-sequential retrieval, since you go from the beginning without any skips.)

You can display the RBA of a record after you issue a GET or a POINT, as well as after you issue a PUT.
Example: Skip-Sequential Insertion

In this example, one PUT macro is used to insert multiple fixed-length, 100-byte records. Records are to be moved asynchronously from a work area.

```
OUTPUT ACB MACRF=(KEY,SKP, OUT)

.
.

```

Generation or modification failed. Display the feedback field in each request parameter list to find out which one had an error.

```
WORK DS CL500
```

Contains five 100-byte work areas.
You give no search argument for storage: VSAM knows the position of the key field in each record and extracts the key from it. Skip sequential insertion differs from keyed-direct insertion in the sequence in which records may be inserted (ascending nonconsecutive sequence versus random sequence) and in performance.

With skip-sequential insertion, if you insert two or more records into a control interval, VSAM doesn’t write the contents of the buffer to direct-access storage until you have inserted all of the records. With direct insertion, VSAM writes the contents of the buffer after you have inserted each record.

Example: Keyed-Direct Insertion

In this example, a PUT macro is used to move fixed-length, 100-byte records from a work area.

```
OUTPUT ACB MACRF=(KEY,DIR,OUT)
DIRECT RPL ACB=OUTPUT,
         AREA=WORK,
         AREALEN=100,
         OPTCD=(KEY,DIR,
                ASY,NUP,MVE),
         RECLEN=100

LOOP PUT RPL=DIRECT
       LTR 15,15
       BNZ NOTACCEP

CHECK RPL=DIRECT
       LTR 15,15
       BNZ ERROR
       B LOOP
NOTACCEP ... Request wasn't accepted.
ERROR ... Request failed.

WORK DS CL100 Work area.
```

The macros are described, as follows:

- ACB specifies that the data set, OUTPUT, into which records are to be inserted, is opened for keyed-direct, output processing.
- RPL specifies that the record to be inserted into the OUTPUT data set resides in a 100-byte area, WORK.

VSAM extracts the key from the key field of each record found at WORK. Using keyed-direct access is very similar to using skip sequential access.
Example: Addressed-Sequential Addition

In this example, a PUT macro is used to add variable-length records to a data set. The data set is assumed to be an entry-sequenced data set because records cannot be inserted into or added to a key-sequenced data set with addressed access.

```
BLOCK ACB MACRF=(ADR,SEQ,OUT)

LIST RPL ACB=BLOCK,
     AREA=NEWRCD,
     AREALEN=100,
     OPTCD=(ADR,SEQ,

```

Build the record.
Put the length of the record into register 3.
Indicate length of new record.
Modification failed.
Request wasn't accepted or failed.
Build record in this work area.

Each record is stored in the next position after the last record in the data set. You do not have to specify an RBA or do any explicit positioning (with the POINT macro). Addressed addition of records is always identical to loading a data set: when additional space is required, VSAM extends the data set.

The only difference between addressed-sequential and addressed-direct addition is when the buffers are written to external storage. The buffer is written to external storage only when it is full for sequential addition; it is written after each record for direct addition. You cannot use direct storage to load records into a data set for the first time; you must use sequential storage.
Example: Keyed-Sequential Update

In this example, GET and PUT macros are used to retrieve and update fixed-length, 50-byte records. Records are updated synchronously in a work area. This example requires the use of a work area because you cannot update a record in the I/O buffer.

```plaintext
UPDATA ACB MACR=(KEY,SEQ,OUT)  
LIST RPL ACB=UPDATA, AREA=WORK, AREALEN=50, OPTCD=(KEY,SEQ,SYN,UPD,MVE)  

.  
.  
LOOP GET RPL=LIST  
LTR 15,15  
BNZ ERROR  
Decide whether to update the record.  
B LOOP Don't update it; retrieve another.  
Do update the record.  
PUT RPL=LIST  
LTR 15,15  
BNZ ERROR  
B LOOP  
ERROR . . . Request wasn't accepted or failed.  
.  
.  
WORK DS CL50 VSAM puts the retrieved record here.  
```

A GET for update (OPTCD=UPD) must precede a PUT for update. Besides retrieving the record to be updated, GET positions VSAM at the record retrieved, in anticipation of the succeeding update (or deletion). It is not necessary for you to store back (or delete) the record that you retrieved for update. VSAM's position at the record previously retrieved allows you to issue another GET to retrieve the following record. You cannot then, however, store back the previous record: the position for update has been forgotten because of the following GET.
Example: Keyed-Direct Update

In this example, GET and PUT macros are used to retrieve and update records. The MODCB macro is used to modify record length (RECLEN) in the request parameter list when an update causes the record length to change. The maximum record length is 120 bytes. The search argument is a full key (five bytes), compared equal.

**INPUT** ACB MACRF=(KEY,DIR,OUT)

**UPDTE** RPL ACB=INPUT, AREA=IN, AREALEN=120, OPTCD=(KEY,DIR,SYN,UPD,KEQ,FKS,MVE), ARG=KEYAREA, KEYLEN=5

**KEYAREA** DS CL5

Search argument for retrieving a record.

**RLNGTH** DS F

Area for displaying the length of a retrieved record.
You cannot update records in the I/O buffer. A direct GET for update positions VSAM at the record retrieved, in anticipation of storing back (or deleting) the record. This positioning also allows you to switch to sequential access to retrieve the next record.

You don't have to store back a record that you retrieve for update, but if you don't store it back before another retrieval, it's too late to do so.

**Example: Addressed-Sequential Update**

In this example, GET and PUT macros are used to retrieve and update records in an entry-sequenced data set. The records are variable in length, maximum 200 bytes. The lengths of the records are not changed by update (the length of a record can never be changed by addressed access).

```assembly

WORK      DS       CL200    Record-processing work area.
RLNGTH    DS       F        Display area for length of records.
```

If you have inactive records in your entry-sequenced data set, you may reuse the space they occupy by retrieving the records for update and restoring a new record in their place.

With a key-sequenced data set, it is not possible to change the length of records by addressed update because the index is not used and VSAM could not split a control interval if required because of changing record length.
Addressed-direct update varies from sequential update in the specification of an RBA for a search argument.

**Example: Mark Records Inactive**

In this example, GET and PUT macros are used to retrieve a record from an entry-sequenced data set and to mark it as inactive. The record is marked as inactive by putting a hexadecimal 'FF' in first byte of a record. The inactive record will not be sequentially retrieved except for update.

```plaintext
ENTRYSEQ ACB MACRF=(ADR,DIR,OUT)
LIST RPL ACB=ENTRYSEQ, AREA=RECORD, AREALLEN=100, OPTCD=(ADR,DIR,SYN,UPD,MVE)

\(\cdots\)

LOOP GET RPL=LIST
LTR 15,15
BNZ ERROR

Decide whether you still want the data in the record.

\(B\) LOOP
MVI RECORD,X'FF'
PUT RPL=LIST
LTR 15,15
BNZ ERROR
B LOOP

ERROR \(\cdots\) Request wasn't accepted or failed.
RECORD DS CL100 Work area for marking records.

Records of an entry-sequenced data set can't be deleted. If a record loses its usefulness for your application, your program can mark it inactive by placing a unique flag in some conventional part of the record so that when your programs retrieve the record thereafter they can recognize and bypass it. You can use the space occupied by an inactive record by retrieving it for update and storing a new record in its place.

**ERASE Macro (Delete a Record)**

The ERASE macro is used with the GET macro to delete records in a key-sequenced or relative record data set.

The format of the ERASE macro is:

```
[ label] ERASE RPL= address
```

where:

*label*

is one to eight characters that provides a symbolic address for the ERASE macro.
**RPL= address**

specifies the address of a request parameter list that defines the request. You may specify the address in register notation (using a register from 1 through 12, enclosed in parentheses) or specify it with an expression that generates a valid relocatable A-type address constant.

**Example: Keyed-Direct Deletion**

In this example, GET and ERASE macros are used to retrieve and delete records. Not every record retrieved for deletion is deleted. The search argument is a full key (5 bytes), compared equal.

```
DELETE ACB MACRF=(KEY,DIR,OUT)
LIST RPL ACB=DELETE, AREA=WORK, AREALEN=50, ARG=KEYFIELD, OPTCD=(KEY,DIR,SYN,UPD,MVE,FKS,KEQ)
.

LTR 15,15
BNZ ERROR
B LOOP
ERROR 

Request wasn't accepted or failed.

WORK DS CL50
KEYFIELD DS CL5
```

When you retrieve a record for deletion (OPTCD=UPD, same as retrieval for update), VSAM is positioned at the record retrieved, in anticipation of a succeeding ERASE (or PUT) request for that record. You are not required to issue such a request, though. Another GET request nullifies any previous positioning for deletion or update.

Keyed-sequential retrieval for deletion varies from direct in not using a search argument (except for possible use of the POINT macro). Skip-sequential retrieval for deletion (OPTCD=(SKP,UPD)) has the same effect as direct, but it is faster or slower depending on the number of control intervals separating the records being retrieved.
Example: Addressed-Sequential Deletion

In this example, the ERASE macro is used to delete records from a key-sequenced data set. Not every record retrieved for deletion is deleted. Skipping is effected by POINT macro.

```assembly
DELETE ACB MACRF=(ADR, SEQ, OUT)

REQUEST RPL ACB=DELETE, AREA=WORK, AREALEN=100, ARG=ADDR, OPTCD=(ADR, SEQ, ASY, UPD, MVE)

LOOP ... DECIDE WHETHER YOU NEED TO SKIP TO ANOTHER POSITION (FORWARD OR BACKWARD).

ADDR DS F RBA SEARCH ARGUMENT FOR POINT.
WORK DS CL100 WORK AREA.
```

Addressed deletion is allowed only for a key-sequenced data set. The records of an entry-sequenced data set are fixed. When records are deleted using addressed deletion from a key-sequenced data set, the index is not updated.
The POINT macro is used to position for access.

The format of the POINT macro is:

```
[ label ]  POINT  RPL= address
```

where:

- `label` is one to eight characters that provides a symbolic address for the POINT macro.
- `RPL= address` specifies the address of the request parameter list that defines the request. You may specify the address in register notation (using a register from 1 through 12, enclosed in parentheses) or specify it with an expression that generates a valid relocatable A-type address constant.

Example: Position with POINT

In this example, the POINT macro is used to position at a record identified by a full key (five-byte) search argument, compared equal.

```
BLOCK  ACB  DDNAME=IO

POSITION RPL
  ACB=BLOCK,
  AREA=WORK,
  AREALEN=50,
  ARG=SRCHKEY,
  OPTCD={KEY,SEQ,SYN,KEQ,FKS}
  RPL=POSITION

    LTR   15,15
    BNZ   ERROR

Process the record. Decide whether to skip to another position (forward or backward).

B     LOOP
  B     LOOP1
ERROR ...

```

Yes, skip.

No, continue in consecutive sequence.

Request wasn’t accepted or failed.

```
SRCHKEY DS  CL5

Search-argument field for POINT request.

WORK DS  CL50

VSAM puts a record here for each GET request.

```

Search argument for positioning, moved in from a table or a transaction record.
No access is gained to a record with POINT. POINT causes VSAM to be positioned ahead or back to the specified record for a subsequent sequential GET request, which retrieves the record. If, after positioning, you issue a direct request by way of the same request parameter list, VSAM doesn't remember the position established by the POINT. VSAM would then either be positioned somewhere else or not positioned at all, depending on whether OPTCD=NSP or UPD was specified or OPTCD=NUP.

Positioning by address is identical to positioning by key, except that the search argument is an RBA, which must be matched equal to the RBA of a record in the data set.

When a POINT is issued for a subsequent VSAM request, both the POINT and the request must be in the same processing mode.

CHECK Macro (Suspend Processing)

The CHECK macro is used to suspend processing to await the completion of VSAM's processing of the request.

The format of the CHECK macro is:

```
[label] CHECK RPL=address
```

where:

`label`

is one to eight characters that provides a symbolic address for the CHECK macro.

`RPL= address`

specifies the address of the request parameter list that defines the request. You may specify the address in register notation (using a register from 1 through 12, enclosed in parentheses) or specify it with an expression that generates a valid relocatable A-type address constant.
Example: Check Return Codes after an Asynchronous Request

In this example, return codes are checked after an asynchronous request. The CHECK macro is used to cause an exit to be taken if there is a logical or physical error or if the end of the data set is reached.

```
REQPARMS RPL OPTCD=ASY
  . RPL=REQPARMS
  .
  GET LTR 15,15
  BNZ REJECTED

CHECK RPL=REQPARMS
  LTR 15,15
  BNZ FAILURE

REJECTED ...

FAILURE ...
```

Was the request completed successfully?

Zero indicates the request was accepted. If it wasn't accepted, register 15 contains 4: REQPARMS is active for another request. Continue to work on something that is not dependent on the request.

CHECK would cause one of the three exits to be taken if there was a logical or physical error or if the end of the data set was reached and an active exit list exists.

Test return indication in register 15.

Zero indicates the request completed successfully. If it failed, register 15 contains 8 or 12: there was a logical or a physical error.

Always test register 15 after the CHECK unless you provide exit routines that terminate processing. If a routine returns to VSAM, register 15 is reset and control is passed back to your program immediately after the CHECK. An error-analysis routine normally issues SHOWCB or TESTCB to examine the feedback field in the request parameter list, so that when your processing program gets control back, it doesn't have to analyze the error—but it may alter its processing if there was an error. If you don't provide an error-analysis routine, your program can issue SHOWCB or TESTCB to analyze an error when it gets control back following the CHECK.

Example: Check Return Codes after a Synchronous Request

With synchronous processing, you should test register 15 after the request because the request may not have been accepted (register 15 contains 4) or because an error might have occurred (8 or 12):

```
GET RPL=REQPARMS
LTR 15,15
BNZ REJFAIL

REJFAIL ...
```

Was the request completed successfully?

If branch isn't taken, request was accepted and completed successfully.
Example: Overlap Processing

In this example, the CHECK macro is used to await completion of a request before continuing to other processing. Access is asynchronous.

```
BLOCK ACB
LIST RPL ACB=BLOCK,
      AREA=WORK,
      AREALEN=50,
      OPTCD=ASY
      .
      .

LOOP GET RPL=LIST
LTR 15,15
BNZ NOTACCEP

Do other processing.
CHECK RPL=LIST
      LTR 15,15
      BNZ ERROR

Process the record.
B LOOP

NOTACCEP . . Request wasn't accepted.
ERROR . . Request failed.

WORK DS CL50 Work area.
```

After issuing the request, make sure that VSAM accepted it before you go on to do other processing. When you have done as much other processing as you can, issue the CHECK macro. VSAM will not give you back control now until the request is complete. If you don’t want to issue CHECK until you know the request is complete, use the ECB operand of the RPL macro or the IO=COMPLETE operand of the TESTCB macro. After you issue the CHECK, VSAM immediately returns a code and takes an exit, if necessary. See “RPL Macro (Generate a Request Parameter List)” and “GENCB Macro (Generate a Request Parameter List)” in the chapter “Control Block Macros” for information on the ECB operand.
Example: Suspend a Request for Many Records

In this example, a CHECK macro is issued for the first request parameter list in a chain of parameter lists. If an error occurred for one of the request parameter lists in the chain and you have supplied error-analysis routines, VSAM takes a LERAD or SYNAD exit before it returns control to your program after the CHECK.

LOOP GET RPL=FIRST
LTR 15,15
BNZ NOTACCEP

Do other processing.

CHECK RPL=FIRST
LTR 15,15
BNZ ERROR

Process the three records retrieved by the GET.

B LOOP
NOTACCEP ... Request wasn't accepted.
ERROR ... Display the feedback field (FIELDS=FDBK) of each request parameter list to find out which one had an error.

AREA1 DS CL50 A single GET request causes VSAM to put a record in each of AREA1, AREA2, and AREA3.

AREA2 DS CL50
AREA3 DS CL50

After the CHECK, register 15 is set to indicate the status of the request. A code of 0 indicates that no error was associated with any of the request parameter lists. Any other code indicates that an error occurred for one of the request parameter lists. You should issue a SHOWCB macro for each request parameter list in the chain to find out which one had an error. VSAM doesn't process any of the request parameter lists beyond the one with an error.
ENDREQ Macro (Terminate a Request)

The ENDREQ macro is used to terminate a request.

The format of the ENDREQ macro is:

```
[label]  ENDREQ  RPL=address
```

where:

- **label**
  - is one to eight characters that provides a symbolic address for the ENDREQ macro.

- **RPL= address**
  - specifies the address of the request parameter list that defines the request. You may specify the address in register notation (using a register from 1 through 12, enclosed in parentheses) or specify it with an expression that generates a valid relocatable A-type address constant.

Example: Release Positioning for Another Request

In this example, the ENDREQ macro is used to cause VSAM to release positioning for a request parameter list. There are three request parameter lists, all of which require VSAM to have the ability to remember its position, one only temporarily and two until VSAM is explicitly requested to forget its position. VSAM is given the ability to remember only two positions concurrently (STRNO=2).

<table>

</tr>
<tr>
<td>BNZ</td>
<td>ERROR</td>
<td></td>
</tr>
</tbody>
</table>

VSAM must remember its position. VSAM must remember its position until explicitly requested to forget it by PUT or ENDREQ. VSAM must be able to temporarily remember its position. VSAM now remembers its position for this request. VSAM remembers its position for this request only while it is processing the request. VSAM can therefore remember its position for this request, even though STRNO=2.
Decide whether to update the record.

**B** FORGET

**PUT** RPL=DIRUPD

**LTR** 15, 15

**BNZ** ERROR

**B** LOOP

**FORGET** ENDREQ RPL=DIRUPD

**LTR** 15, 15

**BNZ** ERROR

**B** LOOP

**ERROR** ... Request wasn't accepted or failed.

The use of ENDREQ illustrated here is to cause VSAM to forget its position for one request parameter list so a request defined by another request parameter list can be issued. When PUT is issued after a DIRUPD GET request, ENDREQ need not be issued, since PUT causes VSAM to forget its position (the next DIRUPD GET doesn’t depend on VSAM’s remembering its position). You need to cause VSAM to forget its position when you have issued requests for as many request parameter lists requiring concurrent positioning as the number you specified for STRNO (in the ACB macro) and you want to issue a request for yet another request parameter list. In the example, DIRNUP cannot be reissued unless VSAM is freed from remembering its position for either SEQ or DIRUPD. VSAM remembers its position for SEQ because SEQ’s requests are sequential and depend on VSAM’s remembering its position. Another result of ENDREQ is that buffers are written out if required.

To cause VSAM to give up its position associated with a chain of request parameter lists, specify the first request parameter list in the chain in your ENDREQ macro.

ENDREQ can also be used to cancel an asynchronous request—rather than suspending processing with CHECK. But simply ignoring a request whose completion you are not interested in is adequate.

Because VSAM remembers its position after a direct GET with OPTC=UPD, if no PUT or ENDREQ follows, you can switch to sequential access and use the positioning for a GET.

---

VSAM, through its ISAM interface program, enables a debugged program that processes an indexed-sequential data set to process a key-sequenced data set. The key-sequenced data set may have been converted from an indexed-sequential or a sequential data set (or another VSAM data set) or may have been loaded by one of your own programs. The loading program may be coded with VSAM macros or with ISAM macros or PL/I or COBOL statements. That is, you can load records into a newly defined key-sequenced data set with a program that was coded to load records into an indexed-sequential data set.

There are some minor restrictions on the types of processing an ISAM program may do if it is to be able to process a key-sequenced data set. These restrictions are described in "Restrictions in the Use of the ISAM Interface" later in this chapter.

Significant performance improvement can be gained by modifying an ISAM program that issues multiple OPEN and CLOSE macros to switch between a QISAM and BISAM DCB. The ISAM program can be modified to open the QISAM and BISAM DCBs at the beginning of the program and to close them when all processing is complete. The performance improvement is proportional to the frequency of OPEN and CLOSE macros in the ISAM program.

Figure 13 shows the relationship between ISAM programs processing VSAM data with the ISAM interface and VSAM programs processing the data.
How an ISAM Program Can Process a VSAM Data Set

When a processing program that uses ISAM (assembler-language macros, PL/I or COBOL) issues an OPEN to open a key-sequenced data set, the ISAM interface is given control to:

- Construct control blocks that are required by VSAM.
- Load the appropriate ISAM interface routines into virtual storage.
- Initialize the ISAM DCB (data control block) to enable the interface to intercept ISAM requests.
- Take the DCB exit requested by the processing program.

The ISAM interface intercepts each subsequent ISAM request, analyzes it to determine the equivalent keyed VSAM request, defines the keyed VSAM request in a request parameter list, and initiates the request.

The ISAM interface receives return codes and exception codes for logical and physical errors from VSAM, translates them to ISAM codes, and routes them to the processing program or error-analysis (SYNAD) routine by way of the ISAM DCB or DECB. Figure 14 shows QISAM error conditions and the meaning they have when the ISAM interface is being used.

Figure 15 shows BISAM error conditions and the meaning they have when the ISAM interface is being used.

If invalid requests occur in BISAM that didn't occur previously and the request parameter list indicates that VSAM isn't able to handle concurrent data-set positioning, the value specified for the STRNO AMP parameter should be increased. If the request parameter list indicates an exclusive-use conflict, reevaluate the share options associated with the data.

Figure 16 gives the contents of registers 0 and 1 when a SYNAD routine specified in a DCB gets control.

You may also specify a SYNAD routine by way of the DD AMP parameter (see "JCL for Processing with the ISAM Interface" later in this chapter). Figure 17 gives the contents of registers 0 and 1 when a SYNAD routine specified by way of AMP gets control.

Figure 16. Register Contents for DCB-Specified ISAM SYNAD Routine
If your SYNAD routine issues the SYNADAF macro, registers 0 and 1 are used to communicate. When you issue SYNADAF, register 0 must have the same contents it had when the SYNAD routine got control and register 1 must contain the address of the DCB.

When you get control back from SYNADAF, the registers have the same contents they would have if your program were processing an indexed-sequential data set: register 0 contains a completion code and register 1 contains the address of the SYNADAF message.

The completion codes and the format of a SYNADAF message are given in *OS/VS Data Management Macro Instructions*.

Figure 18 shows abnormal-end (ABEND) codes issued by the ISAM interface when there is no other method of communicating the error to the user.

If a SYNAD routine specified by way of AMP issues the SYNADAF macro, the operand ACSMETH may specify either QISAM or BISAM, regardless of which of the two is used by your processing program.

A dummy DEB is built by the ISAM interface to support:
- References by the ISAM processing program
- Checkpoint/restart
- Abnormal end

Converting an Indexed-Sequential Data Set

Access Method Services is used to convert an indexed-sequential data set to a key-sequenced data set. Assuming that a master and/or user catalog has been defined, define a key-sequenced data set with the attributes, performance options, etc., that you want and then you use the Access Method Services REPRO command to convert the indexed-sequential records and load them into the key-sequenced data set. See the appropriate Access Method Services publication for information about defining a key-sequenced data set and about converting an indexed-sequential data set. VSAM builds the index for the key-sequenced data set as it loads the data set.

Each volume of a multivolume component must be on the same type of device; the data component and the index component, however, may be on volumes of devices of different types.

When you define the key-sequenced data set into which the indexed-sequential data set is to be copied, you must specify the attributes of the VSAM data set for variable- and fixed-length records. For variable-length records:

- VSAM record length equals ISAM DCBLRECL-4
- VSAM key length equals ISAM DCBKEYLE
- VSAM key position equals ISAM DCRKP-4

For fixed-length records:

- VSAM record length (average and maximum must be the same) equals ISAM DCBLRECL (+ DCBKEYLE, if ISAM DCRKP equals 0 and records are unblocked)
- VSAM key length equals ISAM DCBKEYLE
- VSAM key position equals ISAM DCRKP

Care should also be taken with the level of sharing allowed when the key-sequenced data set is defined. If the ISAM program opens multiple DCBs pointing to different DD statements, a share-options value of 1, which is the default, allows only the first DD statement to be opened. See the appropriate Access Method Services publication for a description of the share-options values.
**JCL for Converting from ISAM to VSAM**

In VS1 and VS2 systems, JCL is used to identify data sets and volumes for allocation. In a VS2 system, data sets can also be allocated dynamically. See *OS/VS2 JCL* and *OS/VS2 System Programming Library: TSO* for a description of dynamic allocation.

If JCL is used to describe an indexed-sequential data set to be converted to VSAM using the Access Method Services REPRO command, include DCB=DSORG=IS. The key-sequenced data set that is to receive the converted data set need not be described in JCL if it is to reside in a previously defined data space. If it is to reside alone in a data space, the data set is either allocated dynamically by name (in which case the volume on which it is to reside must be mounted) in a VS2 system or is defined in a DD statement in VS1 or VS2 that includes DISP=OLD, volume and unit information, the AMP parameter, and DSNAME=dsname, where dsname is the name of the key-sequenced data set. In a VS1 or VS2 system, use a STEPCAT or JOBCAT DD statement as described in the chapter “Opening and Closing a Data Set” to make user catalogs available; in a VS2 system, you may also use dynamic allocation.

With ISAM, deleted records are flagged as deleted, but are not actually removed from the data set. If your program depends upon a record’s only being flagged and not actually removed, you may want to keep these flagged records when you convert and continue to have your programs process these records. The Access Method Services REPRO command has a parameter (ENVIRONMENT) that causes VSAM to keep the flagged records when you convert.

**JCL for Processing with the ISAM Interface**

To execute your ISAM processing program to process a key-sequenced data set, replace the ISAM DD card with a VSAM DD card using the DDNAME that was used for ISAM. The VSAM DD card names key-sequenced data set and gives any necessary VSAM parameters (by way of AMP). Specify DISP=MOD for resume loading and DISP=OLD for all other processing. You don't have to specify anything about the ISAM interface itself. The interface is automatically brought into action when your processing program opens a DCB whose associated DD statement describes a key-sequenced data set (instead of an indexed-sequential data set). If you have defined your VSAM data set in a user catalog, specify the user catalog in a JOBCAT or STEPCAT DD statement.

The DCB parameter in the DD statement that identifies a VSAM data set is invalid. Certain DCB-type information may be specified in the AMP parameter, which is described later in this chapter.

Figure 20 shows the DCB fields supported by the ISAM Interface.

Figure 20 (Part 1 of 2). DCB Fields Supported by ISAM Interface
AMP Parameter Specification

When an ISAM processing program is run with the ISAM interface, the AMP parameter enables you to specify:

- The need for extra index buffers for simulating the residency of the highest level(s) of an index in virtual storage (BUFNI)
- Whether to remove records flagged (OPTCD)
- What record format (RECFM) is used by the processing program
- The number of concurrent BISAM and QISAM (basic and queued indexed-sequential access methods) requests that the processing program may issue (STRNO)
- The name of an ISAM exit routine to analyze physical and logical errors (SYNAD)

The AMP parameter has some subparameters that are peculiar to the ISAM interface. The other subparameters of AMP (AMORG, BUFND, BUFSER, CROPS, and TRACE), which can also be used with the interface, are described in “How to Code JCL” in the chapter “Opening and Closing a Data Set.” The format of the AMP parameter (with the subparameters discussed here) is:

```plaintext
  //... DD ...
  [AMP=’AMORG’[, ‘BUFNI= number’]]
  [,’OPTCD={I | L | IL}’]
  [,’RECFM= {F | FB | V | VB}’]
  [,’STRNO= number’]
  [,’SYNAD= modulename’]]
```

where:

**AMORG**

specifies that a VSAM data set is to be processed.

**BUFNI=number**

specifies the number of I/O buffers VSAM is to use for index records. If you don't specify BUFNI, VSAM uses as many index buffers as the number specified for STRNO (1 if you don't specify STRNO). You may specify for BUFNI a number 1 greater than STRNO (2 if you don't specify STRNO) to simulate having the highest level of an ISAM index resident. If you specify for BUFNI a number 2 or more greater than STRNO, you simulate having intermediate levels of the index resident.
\textbf{OPTCD=\{I | L | IL\}}

specifies how records flagged for deletion are to be treated. The values that can be specified are:

\textbf{L}

specifies that a record marked for deletion by your processing program is to be kept in the data set. Although this parameter has the same meaning and restrictions for the ISAM interface as it has for ISAM, it may have to be specified in the AMP parameter when it wasn’t previously needed in the ISAM job control language. It is required when OPTCD=L is not specified in the DCB in the processing program because OPTCD is not merged into the DSCB when the ISAM interface is used.

\textbf{I}

specifies, when coded along with OPTCD=L in the DCB, that records marked for deletion by your processing program are not written into the data set by the ISAM interface. If OPTCD=I is specified in the AMP parameter, but OPTCD=L isn’t specified in the processing program’s DCB, records flagged for deletion are treated like any other records: that is, AMP=’OPTCD=I’, without L anywhere specified, has no effect.

\textbf{IL}

specifies that if your processing program writes a record marked for deletion, the ISAM interface is not to put the record into the data set. (It issues a VSAM ERASE to delete the old record if your processing program had previously read the record for update.) The result of this parameter is the same as when AMP=’OPTCD=I’ is coded along with OPTCD=L in the DCB in the processing program.

\textbf{RECFM=\{F | FB | V | VB\}}

specifies the ISAM record format that your processing program is coded for. Although this parameter has the same meaning and restrictions for the ISAM interface as it has for ISAM, it may have to be specified in the AMP parameter when it wasn’t previously required in the ISAM job control language. RECFM is required when it is not specified in the DCB in the processing program because RECFM is not merged into the DSCB when the ISAM interface is used. All VSAM requests are for unblocked records. If your program issues a request for blocked records, the ISAM interface sets the overflow-record indicator for each record to indicate that each is being passed to your program unblocked. If RECFM isn’t specified in the AMP parameter or in the processing program’s DCB, V is the default.

\textbf{STRNO=number}

specifies the number of request parameter lists the processing program can tie up concurrently. Neither VSAM nor the ISAM interface can anticipate the number, so you must indicate it in the STRNO parameter. Specify a number at least equal to the number of BISAM and QISAM requests that your program can issue concurrently. (If you have subtasks, add the number of such requests for each subtask together, plus an additional one for each subtask that sequentially processes the same data set.) In a create step, STRNO cannot be greater than 1.
**SYNAD=modulename**

specifies the name of a routine that the ISAM interface is to load and exit to if a physical or logical error occurs when you are gaining access to the key-sequenced data set. If your processing program already indicates a SYNAD routine, the routine specified in the AMP SYNAD parameter replaces it.

The ISAM interface uses a request parameter list to describe a request that your program issues. The interface uses the same request parameter list over and over:

- With BISAM, a READ for update ties up a request parameter list until a WRITE or FREEDBUF is issued (at which time the interface issues an ENDREQ for the request parameter list).

- With OISAM, a request parameter list is tied up until an ESETL is issued (at which time the interface issues ENDREQ).

If the processing program issues an ISAM request when no more request parameter lists are available, the ISAM interface returns an ISAM code that indicates an invalid request. If you're running subtasks, it's possible to reissue the invalid request and have it complete successfully when another subtask frees a request parameter list.

The SYNAD routine must not issue VSAM macros or check for VSAM return codes. The ISAM interface translates all VSAM codes to appropriate ISAM codes.

You need not modify or replace a SYNAD routine that issues only a CLOSE, ABEND, SYNADAF, or SYNADRLS macro or merely examines DCB or DECB exception codes.

### Restrictions in the Use of the ISAM Interface

Some restrictions were indicated earlier in this chapter that may require you to modify an ISAM processing program to process a key-sequenced data set. All VS and VSAM restrictions apply to the use of the ISAM interface; for example:

- VSAM doesn't allow the OPENJ macro: if your program issues it, remove it or replace it with the OPEN macro.

- If your processing program was coded on the assumption that the indexed-sequential data set it was processing was a temporary data set, you may need to modify the program: a VSAM data set cannot be temporary.

Additional restrictions are:

- A program must run successfully under ISAM; the interface doesn't check for parameters that are invalid for ISAM.

- If your ISAM program creates dummy records with a maximum key to avoid overflow, remove that code for VSAM.

- If your program counts overflow records to determine reorganization needs, its results will be meaningless with VSAM data sets.

- The work area into which data records are read must not be shorter than a record. If your processing program is designed to read a portion of a record into a work area, you must change the design. The interface takes the record length indicated in the DCB to be the actual length of the data.
record. The record length in a BISAM DECB is ignored except when you are replacing a variable-length record with the WRITE macro.

- You may share data among subtasks that specify the same DD statement in their DCB(s), and VSAM ensures data integrity. But if you share data among subtasks that specify different DD statements for the data, you are responsible for data integrity. The ISAM interface doesn't ensure DCB integrity when two or more DCBs are opened for a data set. Not all of the fields in a DCB can be counted on to contain valid information.

- If your processing program issues the SETL I or SETL ID instruction, you must modify the instruction to some other form of the SETL or take it out. The ISAM interface cannot translate a request that depends on a specific block or device address.

- Although asynchronous processing may be specified in an ISAM processing program, all ISAM requests are handled synchronously by the ISAM interface; WAIT and CHECK requests are always satisfied immediately. The ISAM CHECK macro doesn't result in a VSAM CHECK macro's being issued but merely causes exception codes in the DECB (data event control block) to be tested.

- For processing programs that use locate processing, the ISAM interface constructs buffers to simulate locate processing.

- For blocked-record processing, the ISAM interface simulates unblocked-record processing by setting the overflow-record indicator for each record. (In ISAM, an overflow record is never blocked with other records.) The ISAM RELSE instruction causes no action to take place.

- If your ISAM SYNAD routine examines information that cannot be supported by the ISAM interface (for example, the IOB), specify a replacement ISAM SYNAD routine in the AMP parameter of the VSAM DD statement.

- Dynamic allocation with TSO (use LOGON PROC).

- CATALOG/DADSM macros in the ISAM processing program must be replaced with Access Method Services commands.

**Example: Converting a Data Set**

In this example, the indexed-sequential data set to be converted (ISAMDATA) is cataloged either in the system catalog or in a VSAM catalog. A key-sequenced data set, VSAMDATA, has previously been defined in user catalog USERCTLG. Because both the indexed-sequential and key-sequenced data set are cataloged, unit and volume information need not be specified.

ISAUDIO DATA contains records flagged for deletion; these records are to be kept in the VSAM data set.

```assembler
//CONVERT JOB ...
//JOBCAT DD DISP=SHR,DSNAME=USERCTLG
//STEP EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=A
//ISAM DD DISP=OLD,DSNAME=ISAMDATA,DCB=DSORG=IS
//VSAM DD DISP=OLD,DSNAME=VSAMDATA
//SYSSIN DD *
    REPRO INFILe(ISAM ENVIRONMENT(DUMMY))
    OUTFILE(VSAM)
/*
```
To drop records flagged for deletion in the indexed-sequential data set, omit ENVIRONMENT(DUMMY).

**Example: Issuing a SYNADAF Macro**

The following example illustrates how a SYNAD routine specified by way of AMP may issue a SYNADAF macro without preliminaries—registers 0 and 1 already contain what SYNADAF expects to find.

```fortran
AMPSYN CSECT
    USING *,15
    SYNADAF ACVMETH=QISAM
    STM 14,12,12(13)
    BALR 7,0
    USING *,7
    L 15,132(1)
    L 14,128(1)
    TM 42(15),X'40'
    BO QISAM
    TM 43(15),X'40'
    BO QISAM
BISAM TM 24(14),X'10'
    BO INVQISAM
    .
    .
QISAM TM 80(15),X'10'
    BO INVQISAM
    .
    .
INVQISAM EQU *
INVQISAM EQU *
    LM 14,12,12(13)
DROP 7
    USING AMPSYN,15
SYNADRLS
BR 14
END AMPSYN
```

When the processing program closes the data set, the interface issues VSAM PUT macros for ISAM PUT locate requests (in load mode), deletes the interface routines from virtual storage, frees virtual-storage space that was obtained for the interface, and gives control to VSAM.
USER-WRITTEN EXIT ROUTINES

User-written routines may be supplied to:

- Analyze logical errors
- Analyze physical errors
- Perform end-of-data processing
- Record transactions made against a data set
- Perform user-security verification

**LERAD Exit Routine to Analyze Logical Errors**

A LERAD routine should examine the feedback field in the request parameter list to determine what logical error occurred. What the routine does after determining the error depends on your knowledge of the kinds of things in the processing program that may have caused the error. After a logical error is corrected, return to VSAM. If the error cannot be corrected, close the data set and either terminate processing or return to VSAM.

Figure 21 gives the contents of the registers when VSAM exits to the LERAD routine.

<table>
<thead>
<tr>
<th>Reg.</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Unpredictable.</td>

<tr>
<td>1</td>
<td>Address of the request parameter list that contains the feedback field the routine should examine. The register must contain this address if you return to VSAM.</td>
</tr>
<tr>
<td>2-13</td>
<td>Same as when the request macro was issued. Register 13, by convention, contains the address of your processing program's 72-byte save area, which may not be used as a save area by the LERAD routine if the routine returns control to VSAM.</td>
</tr>
<tr>
<td>14</td>
<td>Return address to VSAM.</td>
</tr>
<tr>
<td>15</td>
<td>Entry address to the LERAD routine. The register doesn't contain the logical-error indicator.</td>
</tr>
</tbody>
</table>

Figure 21. Contents of Registers at Entry to LERAD

If the exit routine issues GENCB, MODCB, SHOWCB, or TESTCB and returns to VSAM, it must provide a save area and restore registers 13 and 14, which are used by these macros.

If a logical error occurs and no LERAD routine is provided (or the LERAD exit is inactive), VSAM returns codes in register 15 and in the feedback field of the request parameter list to identify the error. See "Logical Errors" in the chapter "Request Macros" for a description of these return codes.

**SYNAD Exit Routine to Analyze Physical Errors**

VSAM exits to a SYNAD routine if a physical error occurs when you request access to data. It also exits to a SYNAD routine when you close a data set if a physical error occurs while VSAM is writing the contents of a buffer out to direct-access storage.

A SYNAD routine should examine the feedback field in the request parameter list to identify the type of physical error that occurred. It should then get the address of the message area, if any, from the request parameter list.
list, so that it can examine the message for detailed information about the error.

The main problem with a physical error is the possible loss of data. You should try to recover your data before continuing to process. Input operations (ACB MACRF=IN) are generally less serious than output or update operations (MACRF=OUT), because your request was not attempting to alter the contents of the data set.

If the routine cannot correct an error, it might print the physical-error message, close the data set, and terminate the program. If the error occurred while VSAM was closing the data set, and if another error occurs after the exit routine issues a CLOSE macro, VSAM doesn't exit to the routine a second time.

If the SYNAD routine returns to VSAM, whether the error was corrected or not, VSAM drops the request and returns to your processing program at the instruction following the last executed instruction. Register 15 is reset to indicate that there was an error, and the feedback field in the request parameter list identifies it.

Physical errors affect positioning: if a GET was issued that would have positioned VSAM for a subsequent sequential GET and an error occurs, VSAM is positioned at the control interval next in key (RPL OPTCD=KEY) or in entry (OPTCD=ADR) sequence after the control interval involved in the error. The processing program can therefore ignore the error and proceed with sequential processing. With direct processing, the likelihood of reencountering the control interval involved in the error depends on your application.

Figure 22 gives the contents of the registers when VSAM exits to the SYNAD routine.

<table>
<thead>
<tr>
<th>Reg.</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Unpredictable.</td>
</tr>
<tr>
<td>1</td>
<td>Address of the request parameter list that contains a feedback return code and the address of a message area, if any. If you issued a request macro, the request parameter list is the one pointed to by the request macro; if you issued a CLOSE macro, the request parameter list was built by VSAM to process the close request. Register 1 must contain this address if the SYNAD routine returns to VSAM.</td>
</tr>
<tr>
<td>2-13</td>
<td>Same as when the request macro or CLOSE macro was issued. Register 13, by convention, contains the address of your processing program's 72-byte save area, which may not be used by the SYNAD routine if it returns control to VSAM.</td>
</tr>
<tr>
<td>14</td>
<td>Return address to VSAM.</td>
</tr>
<tr>
<td>15</td>
<td>Entry address to the SYNAD routine. The register doesn't contain the physical-error indicator.</td>
</tr>
</tbody>
</table>

Figure 22. Contents of Registers at Entry to SYNAD

If the exit routine issues GENCB, MODCB, SHOWCB, or TESTCB and returns to VSAM, it must provide a save area and restore registers 13 and 14, which are used by these macros.

See “Physical Errors” in the chapter “Request Macros” for the format of a physical-error message that can be written by the SYNAD routine.

If a physical error occurs and no SYNAD routine is provided (or the SYNAD exit is inactive), VSAM returns codes in register 15 and in the feedback field.
of the request parameter list to identify the error. See “Physical Errors” in the chapter “Request Macros” for a description of these return codes.

**Exception Exit Routine**

You can provide an exception exit routine to monitor I/O errors associated with a data set. The name of your routine is specified via the Access Method Services DEFINE command.

If an I/O error occurs while a program with a specified SYNAD routine is processing a data set with a specified exception exit, the exception exit is taken first.

See the appropriate Access Method Services publication for information about how exception exits are established, changed, or nullified.

**EODAD Exit Routine to Process End-of-Data**

VSAM exits to an EODAD routine when an attempt is made to sequentially retrieve or point to a record beyond the last record in the data set (one with the highest key for keyed access and the one with the highest RBA for addressed access). (VSAM doesn't take the exit for direct requests that specify a record beyond the end.) If the EODAD exit isn't used, the condition is considered a logical error (FDBK code X'04') and can be handled by the LERAD routine, if one is supplied.

The typical actions of an EODAD routine are to issue completion messages, close the data set, and terminate processing without returning to VSAM. If the routine returns to VSAM and another GET request is issued for access to the data set, VSAM exits to the LERAD routine.

If a processing program retrieves records sequentially with a request defined by a chain of request parameter lists, the EODAD routine must determine whether the end of the data set was reached for the first request parameter list in the chain. If not, then one or more records have been retrieved but not yet processed by the processing program.

Figure 23 gives the contents of the registers when VSAM exits to the EODAD routine.

<table>
<thead>
<tr>

</tr>
<tr>
<td>2-13</td>
<td>Same as when the request macro was issued. Register 13, by convention, contains the address of your processing program's 72-byte save area, which may not be used as a save area by the EODAD routine if it returns control to VSAM.</td>
</tr>
<tr>
<td>14</td>
<td>Return address to VSAM.</td>
</tr>
<tr>
<td>15</td>
<td>Entry address to the EODAD routine.</td>
</tr>
</tbody>
</table>

Figure 23. Contents of Registers at Entry to EODAD

If the exit routine issues GENCB, MODCB, SHOWCB, or TESTCB and returns to VSAM, it must provide a save area and restore registers 13 and 14, which are used by these macros.

The type of data set whose end was reached can be determined by examining the request parameter list for the address of the access-method control block.
that connects the program to the data set and testing its ATRB characteristics.

**JRNAD Exit Routine to Journalize Transactions**

A JRNAD routine can be provided to record transactions against a data set and to keep track of changes in the RBAs of records. VSAM takes the JRNAD exit each time the processing program issues a GET, PUT, or ERASE; each time data is shifted right or left in a control interval or is moved to another control interval to accommodate a record's being deleted, inserted, shortened, or lengthened; and path time an I/O error occurs.

Because the JRNAD is taken for I/O errors, a journal exit may zero out, or otherwise alter, the physical-error return code, so that a series of operations may continue to completion, even though one or more of the operations failed.

Figure 24 gives the contents of the registers when VSAM exits to the JRNAD routine.

If the exit routine issues GENCB, MODCB, SHOWCB, or TESTCB, it must restore register 14, which is used by these macros, before it returns to VSAM.

If the exit routine uses register 1, it must restore it with the parameter-list address before returning to VSAM. (The routine must return for completion of the request that caused VSAM to exit.)

For journalizing transactions (when VSAM exits because of a GET, PUT, or ERASE), you can use the SHOWCB macro to display information in the request parameter list about the record that was retrieved, stored, or deleted—FIELDS=(AREA,KEYLEN,RBA,RECLEN), for example. You can also use the TESTCB macro to find out whether a GET or a PUT was for update (OPTCD=UPD).

For recording RBA changes, you must calculate how many records there are in the data being shifted or moved, so you can keep track of the new RBA for each one. With fixed-length records, you calculate the number by dividing the record length into the number of bytes of data being shifted. With variable-length records, you could calculate the number by using a table that not only identifies the records (by associating a record's key with its RBA), but also gives their length.

Some control-interval splits involve data being moved to two new control intervals, and control-area splits normally involve many control intervals' contents being moved. In these cases, VSAM exits to the JRNAD routine for each separate movement of data to a new control interval.

You should provide a routine to keep track of RBA changes caused by control-interval and control-area splits. RBA changes that occur by way of keyed access to a key-sequenced data set must also be recorded if you intend to process the data set later by direct-addressed access.

If your JRNAD routine only journals transactions it should ignore reason X'0C' and return to VSAM; conversely, it should ignore reasons X'00', X'04', and X'08' if it only records RBA changes.

The JRNAD exit must be indicated as active before the data set for which the exit is to be used is opened, and the exit must not be made inactive during processing. If you define more than one access-method control block for a data set and want to have a JRNAD routine, the first ACB you open for the data set must specify the exit list that identifies the routine.
Reg. | Contents
--- | ---
0 | Unpredictable.
1 | Address of a parameter list with the following format:
   4 bytes | Address of the request parameter list that defines the request that caused VSAM to exit to the routine
   4 bytes | Address of a 5-byte field that identifies the data set being processed. This field has the format:
   | 4 bytes Address of the access-method control block that is specified by the request parameter list that defines the request that occasioned the JRNAD exit's being taken
   | 1 byte Indication of whether the data set is the data (X'01') or the index (X'02') component
   4 bytes | For RBA changes only, the RBA of the first byte of data that is being shifted or moved
   4 bytes | For RBA changes only, the number of bytes of data that is being shifted or moved (this number doesn't include free space, if any, or control information—except for a control-area split, when the whole contents of a control interval are moved to a new control interval)
   4 bytes | For RBA changes only, the RBA of the first byte to which data is being shifted or moved
   1 byte | Indication of the reason VSAM exited to the JRNAD routine:
   | X'00' GET request
   | X'04' PUT request
   | X'08' ERASE request
   | X'0C' RBA change
   | X'10' Read spanned record segment
   | X'14' Write spanned record segment
   | X'18' Reserved
   | X'1C' Reserved
   | For shared resources:¹
   | X'20' Control area split
   | X'24' Input error
   | X'28' Output error
   | X'2C' Buffer write
   1 byte | Reserved.
2-13 | Unpredictable.
14 | Return address to VSAM.
15 | Entry address to the JRNAD routine.

¹Described in *OS/VS Virtual Storage Access Method (VSAM Options for Advanced Applications)*.

Figure 24. Contents of Registers at Entry to JRNAD

**User-Security-Verification Routine**

If you use VSAM password protection, you may also have your own routine to check a requester's authority. VSAM transfers control to your routine, which must reside in SYS1.LINKLIB, when a requester gives a correct password other than the master password.

You may, through the Access Method Services DEFINE command, identify your user security-verification routine (USVR) and associate up to 256 bytes of your own security information with each data set to be protected. This information—the user security-authorization record (USAR)—is made available to the USVR when the routine gets control. You may restrict access to the data set as you choose; for example, you may require that the owner of
a data set give his ID when he defines the data set and then allow only the owner to gain access to the data set.

Figure 25 gives the contents of the registers when VSAM gives control to the USVR.

Appendix A: Summary of Macros 157
APPENDIX B: LIST, EXECUTE, AND GENERATE FORMS OF GENCB, MODCB, SHOWCB, AND TESTCB

The standard forms of the GENCB, MODCB, SHOWCB, and TESTCB macros build a parameter list describing in codes the actions indicated by the operands you specify and pass the list to VSAM to take the indicated action. The list, execute, and generate forms of GENCB, MODCB, SHOWCB, and TESTCB allow you to write reentrant programs, share parameter lists, and to modify a parameter list before using it.

Following is a brief description of the list, execute, and generate forms:

- The list form is used to build the parameter list either inline (referred to as *simple list*) or in an area remote from the macro expansion (referred to as *remote list*). Both the simple- and the remote-list forms allow you to build a single parameter list that can be shared.

- The execute form is used to modify a parameter list and to pass it to VSAM for action.

- The generate form is used to build the parameter list in a remote area and to pass it to VSAM for action.

The list, execute, and generate forms of the GENCB, MODCB, SHOWCB, and TESTCB macros have the same format as the standard forms, with the exception of:

- An additional keyword, MF
- Some operands' being optional or not allowed

The sections that follow describe the format of the MF keyword and the use of list, execute, and generate forms. They indicate the optional and required operands.

**List-Form Keyword**

The format of the MF keyword for the list form is:

\[ MF = \{ L | (L, address [, label]) \} \]

where:

- **L** specifies that this is the list form of the macro.
- **address** specifies the address of a remote area in which the parameter list is to be built. The area must begin on a fullword boundary. You can specify the address in register notation or as an expression valid for a relocatable A-type address constant or a direct or indirect S-type address constant.
- **label** is a unique name that is used in an EQU instruction in the expansion of the macro; label is equated to the length of the parameter list. You do not have to know the length of the parameter list if you code label; the expansion of the macro determines the amount of storage required.
Because the MF=L expansion does not include executable code, register notation and expressions that generate S-type address constants cannot be used.

If you code MF=L, the parameter list is built inline, which means that the program is not reentrant if the parameter list is modified at execution.

If you code MF=(L,address), the parameter list is built in the remote area specified, and the area must be large enough for the parameter list.

The size, in fullwords, of a parameter list is:

- For GENCB, 4, plus 3 times the number of ACB, EXLST, or RPL keywords specified (plus 1 for DDNAME, EODAD, JRNAD, LERAD, or SYNAD)
- For MODCB, 3, plus 3 times the number of ACB, EXLST, or RPL keywords specified (plus 1 for DDNAME, EODAD, JRNAD, LERAD, or SYNAD)
- For SHOWCB, 5, plus 2 times the number of fields specified in the FIELDS operand
- For TESTCB, 8 (plus 1 for DDNAME, STMST, EODAD, JRNAD, LERAD, or SYNAD)

If you code MF=(L,address,label), the parameter list is built in the remote area specified. The expansion of the macro equates label with the length of the parameter list.

**Execute-Form Keyword**

The format of the MF keyword for the execute form is:

\[
\text{MF}(E, \text{address})
\]

where:

- \( E \) specifies that this is the execute form of the macro.
- \( \text{address} \) is the address of the parameter list.

The expansion of the execute form of the macro results in executable code that causes:

1. A parameter list to be modified if requested
2. Control to be passed to a routine that satisfies the request

You may not use the execute form to add an entry to a parameter list. If you try to add an entry, an error code of 8 is returned to you in register 15.
Generate-Form Keyword

The format of the MF keyword for the generate form is:

\[ MF = (G, address [, label]) \]

where:

- **G** specifies that this is the generate form of the macro.
- **address** specifies the address of a remote area in which the parameter list is to be built. The area must begin on a fullword boundary.
- **label** is a unique name that is used in an EQU instruction in the expansion of the macro; label is equated to the length of the parameter list. You do not have to know the length of the parameter list if you code label; the expansion of the macro determines the amount of storage required.

If you code \( MF = (G, address) \), the parameter list is built in the remote area specified.

If you code \( MF = (G, address, label) \), the parameter list is built in the remote area specified. The expansion of the macro equates the length of the parameter list to label.

Optional and Required Operands

Keywords that are required in the standard forms of the GENCB, MODCB, SHOWCB, and TESTCB macros may be optional in the list, execute, and generate forms or may not be allowed in the execute form. The meaning of the keywords, however, and the notation that may be used to express addresses, names, numbers, and option codes are the same. See the chapter “Control Block Macros” for the meaning of keywords. See “Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB” for an explanation of how operands may be coded.

List Form of GENCB

The format of the list form of GENCB is:

| [ label ] | GENCB | BLK = {ACB | EXLST | RPL} |
|-----------|-------|---------------------------|
|           |       | [,AM = VSAM]              |
|           |       | [,COPIES = number]        |
|           |       | [,keyword = {address | name | number | option} , ...] |
|           |       | [,LENGTH = number]        |
|           |       | [,MF = {L | (L, address [, label])}] |
|           |       | [,WAREA = address]        |
Execute Form of GENCB

The format of the execute form of GENCB is:

| [label] | GENCB  | BLK={ACB | EXLST | RPL} |
|---------|--------|---------------------------|
|         |        | [,AM=VSAM]                |
|         |        | [,COPIES=number]          |
|         |        | [,keyword={address | name | number | option},...] |
|         |        | [,LENGTH=number]          |
|         |        | ,MF=(E, address)          |
|         |        | [,WAREA=address]          |

Generate Form of GENCB

The format of the generate form of the GENCB macro is:

| [label] | GENCB  | BLK={ACB | EXLST | RPL} |
|---------|--------|---------------------------|
|         |        | [,AM=VSAM]                |
|         |        | [,COPIES=number]          |
|         |        | [,keyword={address | name | number | option},...] |
|         |        | [,LENGTH=number]          |
|         |        | ,MF=(G, address [, label])|
|         |        | [,WAREA=address]          |

List Form of MODCB

The format of the list form of MODCB is:

| [label] | MODCB  | {ACB | EXLST | RPL}=address |
|---------|--------|----------------|
|         |        | ,keyword={address | name | number | option},...] |
|         |        | ,MF={L | (L, address [, label])} |

Execute Form of MODCB

The format of the execute form of MODCB is:

| [label] | MODCB  | {ACB | EXLST | RPL}=address |
|---------|--------|----------------|
|         |        | [,keyword={address | name | number | option},...] |
|         |        | ,MF=(E, address) |

Generate Form of MODCB

The format of the generate form of MODCB is:

| [label] | MODCB  | {ACB | EXLST | RPL}=address |
|---------|--------|----------------|
|         |        | ,keyword={address | name | number | option},...] |
|         |        | ,MF=(G, address [, label]) |
List Form of SHOWCB

The format of the list form of SHOWCB is:

<table>
<thead>
<tr>
<th>label</th>
<th>SHOWCB</th>
</tr>
</thead>
</table>
|       | {
|       |   [ACB | EXLST | RPL] = address |
|       | , AREA = address |
|       | , FIELDS = (keyword [, keyword , ...]) |
|       | , LENGTH = number |
|       | , MF = [L | (L, address [, label])] |
|       | , OBJECT = DATA | INDEX |
|       | } |

Execute Form of SHOWCB

The format of the execute form of SHOWCB is:

<table>
<thead>
<tr>
<th>label</th>
<th>SHOWCB</th>
</tr>
</thead>
</table>
|       | {
|       |   [ACB | EXLST | RPL] = address |
|       | , AREA = address |
|       | , MF = (E, address) |
|       | , OBJECT = DATA | INDEX |
|       | } |

Generate Form of SHOWCB

The format of the generate form of SHOWCB is:

<table>
<thead>
<tr>
<th>label</th>
<th>SHOWCB</th>
</tr>
</thead>
</table>
|       | {
|       |   [ACB | EXLST | RPL] = address |
|       | , AREA = address |
|       | , FIELDS = (keyword [, keyword , ...]) |
|       | , LENGTH = number |
|       | , MF = (G, address [, label]) |
|       | , OBJECT = DATA | INDEX |
|       | } |

List Form of TESTCB

The format of the list form of TESTCB is:

<table>
<thead>
<tr>
<th>label</th>
<th>TESTCB</th>
</tr>
</thead>
</table>
|       | {
|       |   [ACB | EXLST | RPL] = address |
|       | , ERET = address |
|       | , keyword = { address | name | number | option } |
|       | , MF = [L | (L, address [, label])] |
|       | , OBJECT = DATA | INDEX |
|       | } |

Execute Form of TESTCB

The format of the execute form of TESTCB is:

<table>
<thead>
<tr>
<th>label</th>
<th>TESTCB</th>
</tr>
</thead>
</table>
|       | {
|       |   [ACB | EXLST | RPL] = address |
|       | , ERET = address |
|       | , keyword = { address | name | number | option } |
|       | , MF = (E, address) |
|       | , OBJECT = DATA | INDEX |
|       | } |
Generate Form of TESTCB

The format of the generate form of TESTCB is:

| [label] | TESTCB | [{ACB | EXLST | RPL} = address] |
|---------|--------|-------------------------------|
|         |        | [,ERET = address]             |
|         |        | [,keyword = {address | name | number | option}] |
|         |        | [,MF = (G, address[,label])]   |
|         |        | [,OBJECT = {DATA | INDEX}]     |

Use of List, Execute, and Generate Forms

Again, the list, execute, and generate forms allow you to use GENCB, MODCB, SHOWCB, and TESTCB in reentrant programs and allow you to share parameter lists. Figure 26 indicates which forms of these macros should be used in reentrant/nonreentrant and shared/nonshared environments.

<table>
<thead>
<tr>
<th>Reentrant</th>
<th>Nonreentrant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shared</td>
<td>MF = (L, address[, label])</td>
</tr>
<tr>
<td></td>
<td>MF = (E, address)</td>
</tr>
<tr>
<td>Nonshared</td>
<td>MF = (G, address[, label])</td>
</tr>
</tbody>
</table>

The figure shows that:

- To share parameter lists in a reentrant program, the remote-list form should be used in conjunction with the execute form.

- To share parameter lists in a nonreentrant program, the simple-list form should be used in conjunction with the execute form.

- If you do not intend to share parameter lists, the generate form should be used in reentrant programs and the standard form should be used for nonreentrant programs.

The examples that follow illustrate how the list, execute, and generate forms work.

Example: Generate Form

In this example, the generate form of GENCB is used to create a default request parameter list in a reentrant environment.

LA 10, LEN1
GETMAIN R, LV = (10)
LR 2, 1
GENCB BLK = RPL,
       MF = (G, (2), LEN1)

The macro expansion equates LEN1 to the length of the parameter list, as follows:

+LEN1 EQU 16
Example: Remote-List Form

In this example, the remote-list form of MODCB is used to build a parameter list that will later be used to modify the MACRF bits in an access-method control block.

```
LA 8, LEN2      Get length of the parameter list.
GETMAIN R, LV=(8) Get storage for the area in which the parameter list is to be built.
LR 3, 1         Save address of the parameter-list area.
MODCB ACB=ANYACB,
               MACRF=(KEY,DIR),
               MF=(L,(3),LEN2)
```

The macro expansion equates the length of the parameter list to LEN2, as follows:

```
+LEN2 EQU 24
```

Example: Execute Form

In this example, the execute form of MODCB is used to modify the address of the access-method control block and MACRF codes in the parameter list created by the remote-list form of MODCB in the previous example.

```
MODCB ACB=MYACB, MACRF=(ADR,SEQ,OUT), MF=(E,(3))
```

Example: Simple-List and Execute Forms

In this example, the execute form of TESTCB is used to modify a field that was not specified in the list-form TESTCB.

```
TESTCB SYNAD=(,A), MF=(E,PLIST1)
```

Constants

```
PLIST1 TESTCB EXLST=EXL1,LERAD=(LOGERR,A), MF=L
```

The second TESTCB macro is in simple-list form, which causes a parameter list to be built inline. Because the second TESTCB does not include a SYNAD keyword, the first TESTCB, which is in execute form, cannot find a SYNAD entry in the parameter list; a return code of 8 is returned in register 15.
Appendix C: Operand Notation for GENCB, MODCB, SHOWCB, and TESTCB

The addresses, names, numbers, and options required with operands in GENCB, MODCB, SHOWCB, and TESTCB can be expressed in a variety of ways:

- An absolute numeric expression, for example, STRNO=3 and COPIES=10
- A character string, for example, DDNAME=DATASET
- A code or a list of codes separated by commas and enclosed in parentheses, for example, OPTCD=KEY or OPTCD=(KEY,DIR,IN)
- An expression valid for a relocatable A-type address constant, for example, AREA=MYAREA+4
- A register from 2 through 12 that contains an address or numeric value, for example, SYNAD=(3); equated labels can be used to designate a register, for example, SYNAD=(ERR), where the following equate statement has been included in the program: ERR EQU 3
- An expression of the form (S,scon), where scon is an expression valid for an S-type address constant, including the base-displacement form
- An expression of the form (*,scon), where scon is an expression valid for an S-type address constant, including the base-displacement form; the address specified by scon is indirect, that is, it is the address of an area that contains the value of the keyword

If an indirect S-type address constant is used, the value it points to must meet the following criteria:

- If it is a numeric quantity or an address, it must occupy a fullword of storage.
- If it is an alphabetic character string, it must occupy two words of storage, be left aligned, and be filled on the right with blanks.

The expressions that can be used depend on the keyword specified. Additionally, register and S-type address constants cannot be used when MF=L is specified. See “Appendix B: List, Execute, and Generate forms of GENCB, MODCB, SHOWCB, and TESTCB.”
Operands with GENCB

Figure 27 shows the expressions that can be used in the GENCB macro.

GLOSSARY

The following terms are defined as they are used in this book. If you do not find the term you are looking for, refer to the index or to the IBM Data Processing Glossary, GC20-1699.

Access Method Services: A multifunction service program that is used to define VSAM data sets and allocate space for them, convert indexed-sequential data sets to key-sequenced data sets, modify data-set attributes in the catalog, reorganize data sets, facilitate data portability between operating systems, create backup copies of data sets, help make inaccessible data sets accessible, list the records of data sets and catalogs, define and build alternate indexes, and convert OS catalogs to OS/VS2 catalogs.

addressed-direct access: The retrieval or storage of a data record identified by its RBA, independent of the record's location relative to the previously retrieved or stored record. (See also keyed-direct access, addressed-sequential access, and keyed-sequential access.)

addressed-sequential address: The retrieval or storage of a data record in its entry sequence relative to the previously retrieved or stored record. (See also keyed-sequential access, addressed-direct access, and keyed-direct access.)

alternate index: A collection of index entries organized by the alternate keys of its associated base data records. It provides an alternate means of locating records in the data component of a cluster on which the alternate index is based.

alternate key: One or more consecutive characters taken from a data record and used to build an alternate index or to locate one or more base data records via an alternate index. (See also generic key, key, key field, and prime key.)

alternate index cluster: The data and index components of an alternate index.

application: As used in this publication, the use to which an access method is put or the end result that it serves; contrasted to the internal operation of the access method.

base cluster: A key-sequenced or entry-sequenced data set over which one or more alternate indexes are built.

catalog: (See master catalog and user catalog.)

catalog recovery area: (See CRA.)

cluster: A named structure consisting of a group of related components (e.g. a data component with its index component). A cluster may consist of a single component. (See also base cluster and alternate-index cluster.)

collating sequence: An ordering assigned to a set of items, such that any two sets in that assigned order can be collated. As used in this publication, the order defined by the System/370 8-bit code for alphabetic, numeric, and special characters.

component: A named, cataloged collection of stored records. A component, the lowest member of the hierarchy of data structures that can be cataloged, contains no named subsets.

control area: A group of control intervals used as a unit for formatting a data set before adding records to it. Also, in a key-sequenced data set, the set of control intervals pointed to by a sequence-set index record; used by VSAM for distributing free space and for placing a sequence-set index record adjacent to its data.

control-area split: The movement of the contents of some of the control intervals in a control area to a newly created control area, to facilitate the insertion or lengthening of a data record when there are no remaining free control intervals in the original control area.

control interval: A fixed-length area of auxiliary-storage space in which VSAM stores records. It is the unit of information transmitted to or from auxiliary storage by VSAM.

control-interval access: The retrieval or storage of the contents of a control interval.

control-interval split: The movement of some of the stored records in a control interval to a free control interval, to facilitate the insertion or lengthening of a record that won't fit in the original control interval.

CRA: Catalog recovery area. An entry-sequenced data set that exists on each volume owned by a recoverable catalog, including the catalog itself. The CRA contains self-describing records that are duplicates of catalog records that describe the volume.

data integrity: Preservation of data or programs for their intended purpose. As used in this publication, the safety of data from inadvertent destruction or alteration.

data record: A collection of items of information from the standpoint of its use in an application, as a user supplies it to VSAM for storage.

data security: Prevention of access to or use of data or programs without authorization. As used in this publication, the safety of data from unauthorized use, theft, or purposeful destruction.

data set: The major unit of data storage and retrieval in the operating system, consisting of data in a prescribed arrangement and described by control information to which the system has access. As used in this publication, a collection of fixed- or variable-length records in auxiliary storage, arranged by VSAM in key sequence or in entry sequence. (See also key-sequenced data set and entry-sequenced data set.)

data space: A storage area defined in the volume table of contents of a direct-access volume for the exclusive use of VSAM to store data sets, indexes, and catalogs.

direct access: The retrieval or storage of data by a reference to its location in a data set rather than to the previously retrieved or stored data. (See also addressed-direct access and keyed-direct access.)

distributed free space: Space reserved within the control intervals of a key-sequenced data set for inserting new records into the data set in key sequence; also, whole control intervals reserved in a control area for the same purpose.

entry sequence: The order in which data records are physically arranged (according to ascending RBA) in auxiliary storage, without respect to their contents. (Contrast to key sequence.)

entry-sequenced data set: A data set whose records are loaded without respect to their contents, and whose RBAs cannot change. Records are retrieved and stored by addressed access, and new records are added at the end of the data set.
field: In a record or a control block, a specified area used for a particular category of data or control information.

generic key: A high-order portion of a key, containing characters that identify those records that are significant for a certain application. For example, it might be desirable to retrieve all records whose keys begin with the generic key AB, regardless of the full key values.

index: As used in this publication, an ordered collection of pairs, each consisting of a key and a pointer, used by VSAM to sequence and locate the records of a key-sequenced data set.

index record: A collection of index entries that are retrieved and stored as a group. (Contrast to data record.)

ISAM interface: A set of routines that allow a processing program coded to use ISAM (indexed-sequential access method) to gain access to a key-sequenced data set.

job catalog: A catalog made available for a job by means of the JOBCAT DD statement.

key: One or more characters within an item of data that are used to identify it or control its use. As used in this publication, one or more consecutive characters taken from a key sequence set of an index record, data record, stored record.

key field: A field located in the same position in each record of a data set, whose contents are used for the key of a record.

key sequence: The collating sequence of data records, determined by the value of the key field in each of the data records. May be the same as, or different from, the entry sequence of the records.

key-sequenced data set: A data set whose records are loaded in key sequence and controlled by an index. Records are retrieved and stored by keyed access or by address access, and new records are inserted in the data set in key sequence by means of distributed free space. RBAs of records can change.

keyed-direct access: The retrieval or storage of a data record by use of either an index that relates the record's key to its relative location in the data set or a relative record number, independent of the record's location relative to the previously retrieved or stored record. (See also address-direct access, keyed-sequential access, and address-sequential access.)

keyed-sequential access: The retrieval or storage of a data record in its key or relative record sequence relative to the previously retrieved or stored record, as defined by the sequence set of an index. (See also address-sequential access, keyed-direct access, and address-direct access.)

master catalog: A catalog that contains extensive data-set and volume information that VSAM requires to locate data sets, to allocate and deallocate storage space, to verify the authorization of a program or operator to gain access to a data set, and to accumulate usage statistics for data sets.

password: A unique string of characters stored in a catalog that a program, a computer operator, or a terminal user must supply to meet security requirements before a program gains access to a data set.

path: A named, logical entity composed of one or more clusters (an alternate index and its base cluster, for example).

physical record: A physical unit of recording on a medium. For example, the physical unit between address markers on a disk.

pointer: An address or other indication of location. For example, an RBA is a pointer that gives the relative location of a data record or a control interval in the data set to which it belongs.

portability: The ability to use VSAM data sets with different operating systems. Volumes whose data sets are cataloged in a user catalog can be demounted from storage devices of one system, moved to another system, and mounted on storage devices of that system. Individual data sets can be transported between operating systems using Access Method Services.

prime index: The index component of a key-sequenced data set that has one or more alternate indexes. (See also index and alternate index.)

prime key: (See key.)

random access: (See direct access.)

RBA: Relative byte address. The displacement of a data record or a control interval from the beginning of the data set to which it belongs; independent of the manner in which the data set is stored.

record: (See index record, data record, stored record.)

retrievable catalog: A catalog defined with the recoverable attribute. Duplicate catalog entries are put into CRAs that can be used to recover data in the event of catalog failure. (See also CRA.)

relative byte address: (See RBA.)

relative record data set: A data set whose records are loaded into fixed-length slots.

relative record number: A number that identifies not only the slot, or data space, in a relative record data set but also the record occupying the slot. Used as the key for keyed access to a relative record data set.

replication: (See index replication.)

reusable data set: A VSAM data set that can be reused as a work file, regardless of its old contents. Must not be a base cluster.

RPL string: A set of chained RPLs (the set may contain one or more RPLs) used to gain access to a VSAM data set by action macros (GET, PUT, etc). Two or more RPL strings may be used for concurrent direct or sequential requests made from a processing program or its subtasks.

security: (See data security.)

sequence checking: The process of verifying the order of a set of records relative to some field's collating sequence.

sequence set: The lowest level of the index of a key-sequenced data set; it gives the locations of the control intervals in the data set and orders them by the key sequence of the data records they contain. The sequence set and the index set together comprise the index.

sequential access: The retrieval or storage of a data record in either its entry sequence, its key sequence or its relative record number sequence, relative to the previously retrieved or stored record. (See also address-sequential access and keyed-sequential access.)
shared resources: A set of functions that permit the sharing of a pool of I/O-related control blocks, channel programs, and buffers among several VSAM data sets open at the same time.

skip-sequential access: Keyed-sequential retrieval or storage of records here and there throughout a data set, skipping automatically to the desired record or collating position for insertion: VSAM scans the sequence set to find a record or a collating position. Valid for processing in ascending sequences only.

spanned record: A logical record whose length exceeds control interval length, and as a result, crosses, or spans, one or more control interval boundaries within a single control area.

step catalog: A catalog made available for a step by means of the STEPCAT DD statement.

stored record: A data record, together with its control information, as stored in auxiliary storage.

upgrade set: All the alternate indexes that VSAM has been instructed to update whenever there is a change to the data component of the base cluster.

user catalog: An optional catalog used in the same way as the master catalog and pointed to by the master catalog. It also lessens the contention for the master catalog and facilitates volume portability.

vertical pointer: A pointer in an index record of a given level that gives the location of an index record in the next lower level or the location of a control interval in the data set controlled by the index.
INDEX

For additional information about any subject listed in this index, refer to the publications that are listed under the same subject in either OS/VS1 Master Index, GC24-5104, or OS/VS2 Master Index, GC28-0693.

This index makes no page references to the glossary.

  in FIELDS operand 83
  in TESTCB macro 93
function codes 97
FWD option
  in OPTCD operand 56
  relative to POINT macro 22

G
GEN option, in OPTCD operand 56
GENCB macro
  examples 62,65,70
  execute form 162
  generate form 162
  list form 161
  operand notation for 168
  return codes from 42
  used to code a reentrant program 159,164
  used to generate
    access method control block 57
    exit list 63
    request parameter list 65
  generate form 159
    example 164
    of GENCB macro 162
    of MODCB macro 162
    of SHOWCB macro 163
    of TESTCB macro 164
  generating control blocks and lists 41
  generic key (partial key) 22
GET macro 102
  examples 103
  positioning 22
GETIX macro 96
GET-previous processing
  defined 22
  restriction 22
  specifying in RPL macro 56
getting a record
  addressed 25
  keyed 22
  positioning 22
  skipping 23
GSR option, in MACRF operand 49

H
high-level languages 129
journalizing transactions 146
JRNAD exit routine
coding 146
contents of registers at entry 147
journalizing transactions 146
specifying the exit with EXLST macro 51
JRNAD operand
in EXLST macro 51
in FIELDS operand 81
in GENCB macro 63
in MODCB macro 72
in TESTCB macro 90

K
KEY option, in OPTCD operand 56
KEY
alternate 18,19
compressed 19
generic 22
nonunique 19
prime 20
unique 19
KEY option
in MACRF operand 49
in OPTCD operand 56
key sequence 17
key-sequenced data set
comparison with entry-sequenced and relative record data set 18
definition 16
keeping track of relative byte addresses 145
keyed access
addition 24
deletion 24
insertion 24
retrieval 22
skipping 24
storage 24
keyed access to a key-sequenced data set 22
keyed access to a path 22
keyed access to a relative record data set 22
keyed-direct access
examples 107,109,114,116,120
for deletion 24
for retrieval 22
for storage 24
keyed-sequential access
examples 103,109,111,116
for deletion 24
for retrieval 22
for storage 24
KEYLEN operand
in FIELDS operand
length of key field 78
length of search argument 83
in GENCB macro 67
in MODCB macro 74
in RPL macro 54
in TESTCB macro
length of key field 86
length of search argument 92
KGE option, in OPTCD operand 56
KSDS attribute, in ATRB operand 87

L
L option, in EODAD, JRNAD, LERAD, and SYNAD operands
specified in EXLST macro 51
specified in GENCB macro 51
specified in MODCB macro 72
tested in TESTCB macro 91
languages, programming 129
LENGTH operand
in GENCB macro
area for access-method control block 60
area for exit list 64
area for request parameter list 68
in SHOWCB macro
area for access-method control block 76
area for exit list 80
area for request parameter list 82
lengthening a record
changing RBAs 17,146
entry-sequenced data set 18
LERAD exit routine
analyzing logical errors 143
coding 143
contents of registers at entry 143
specifying the exit with EXLST macro 51
LERAD operand
in EXLST macro 51
in FIELDS operand 81
in GENCB macro 63
in MODCB macro 72
in TESTCB macro 90
list form 159
example 165
of GENCB macro 161
of MODCB macro 162
of SHOWCB macro 163
of TESTCB macro 163
load mode, when VSAM data set is empty 49
LOC option, in OPTCD operand 56
locate processing
retrieval 22,25
simulation by ISAM interface 140
logical-error-analysis exit routine 143
logical-error function codes 97
logical-error return codes from request macros 95
lower case, in notational conventions 4
LRD option, in OPTCD operand 56
LRECL operand
in FIELDS operand 78
in TESTCB macro 86
LSR option, in MACRF operand 49

M
MACRF operand
in ACB macro 48
in GENCB macro 61
in MODCB macro 71
in TESTCB macro 88
interaction with PASSWD operand 48,61
restriction with shared control blocks 44
macros, VSAM
(see also Access Method Services)
ACB 44
BLDVRP 149
CHECK 123
Macros, VSAM (continued)

CLOSE 37
control block 41
DLVRP 149
ENDREQ 127
ERASE 119
EXLST 51
GENCB
    used to generate an access-method control block 57
    used to generate an exit list 63
    used to generate a request parameter list 65
GET 102
GETIX 149
MODCB
    used to modify an access-method control block 71
    used to modify an exit list 72
    used to modify a request parameter list 73
OPEN 33
POINT 122
PUT 110
PUTIX 149
return codes from
    control block macros 42
    request macros 95
RPL 52
SCHBFR 149
SHOWCAT 149
SHOWCB
    used to display an access-method control block 75
    used to display an exit list 80
    used to display a request parameter list 82
summary of VSAM macros 149
TESTCB
    used to test an access-method control block 85
    used to test an exit list 90
    used to test a request parameter list 92
WRTBFR 149
maintaining an alternate index 20
making a user catalog available 29
MAREA operand
    in ACB macro 49
    in FIELDS operand 77
    in GENCB macro 60
    in MODCB macro 71
    in TESTCB macro 86
marking records inactive in an entry-sequenced data set,
    example 119
mass sequential insertion 24
master password 34
messages 100
method of indicating the end of a data set 37
MF operand, in GENCB, MODCB, SHOWCB, and TESTCB macros 159
MLEN operand
    in ACB macro 49
    in FIELDS operand 77
    in GENCB macro 60
    in MODCB macro 71
    in TESTCB macro 86
MODCB macro
    examples 72,73,74
    execute form 162
    generate form 162
    list form 162
    operand notation for 169
    return codes from 42
    used to code a reentrant program 159,164
    used to modify
        access-method control block 71,72
        exit list 72
        request parameter list 73
modifying a control block
    access-method control block 71
    exit list 72
    request parameter list 73
monitoring data set errors 145
MRKBFR macro 149
MSGAREA operand
    in FIELDS operand 83
    in GENCB macro 68
    in MODCB macro 74
    in RPL macro 54
    in TESTCB macro 92
MSGLEN operand
    in FIELDS operand 83
    in GENCB macro 68
    in MODCB macro 74
    in RPL macro 54
    in TESTCB macro 92
multiple-request processing
    number of I/O buffers used in 49-50,61
    specifying the number of requests 49-50,61
MVE option, in OPTCD operand 56

N

N option, in EODAD, JRNAD, LERAD, and SYNAD operands
    specified in EXLST macro 51
    specified in GENCB macro 64
    specified in MODCB macro 72
    tested in TESTCB macro 91
NCI option, in MACRF operand 49
NCIS operand
    in FIELDS operand 78
    in TESTCB macro 86
NDELNR operand
    in FIELDS operand 78
    in TESTCB macro 86
NDF option, in MACRF operand 49
NEXCP operand
    in FIELDS operand 78
    in TESTCB macro 86
NEXT operand
    in FIELDS operand 78
    in TESTCB macro 86
NFX option, in MACRF operand 49
NINSR operand
    in FIELDS operand 78
    in TESTCB macro 86
NLOGR operand
    in FIELDS operand 78
    in TESTCB macro 86
NLOGR operand
    in FIELDS operand 78
    in TESTCB macro 86
Index 183
nonunique keys 19
NO option, in CATALOG operand
  in ACB macro 47
  in GENCB macro 60
  in MODCB macro 71
  in TESTCB macro 87
notation, operand, for GENCB, MODCB, SHOWCB, and
  TESTCB macros 167
notational conventions 3
noting RBA changes 145
for control area splits 146
for control interval splits 146
NRETR operand
  in FIELDS operand 78
  in TESTCB macro 86
NRM option, in MACRF operand 49
NRS option, in MACRF operand 49
NSP option, in OPTCD operand 56
NSR option, in MACRF operand 49
NSSS operand
  in FIELDS operand 78
  in TESTCB macro 86
NU option, in MACRF operand 49
NUIW option, in FIELDS operand 78
NUP option, in OPTCD operand 56
NUPDR operand
  in FIELDS operand 78
  in TESTCB macro 86
NXTRPL operand
  in FIELDS operand 83
  in GENCB macro 68
  in MODCB macro 74
  in RPL macro 55
  in TESTCB macro 92
OBJECT operand
  in SHOWCB macro 75
  in TESTCB macro 87
OFIELDS operand, in TESTCB macro 88
OLD, subparameter in JCL 30
OPEN (in OFIELDS operand in TESTCB macro) 88
OPEN macro
  connecting program to data 33
  error return codes from 36
  example 35
  ISAM interface 130,139
OPEN/CLOSE/TCLOSE message area
  in ACB macro 49
  in FIELDS operand 77
  in GENCB macro 60
  in MODCB macro 71
  in TESTCB macro 86
OPENOBJ operand, in TESTCB macro 88
operand notation for GENCB, MODCB, SHOWCB, and
  TESTCB macros 167
OPTCD operand
  in GENCB macro 68
  in MODCB macro 74
  in RPL macro 55,56
  in TESTCB macro 93
  with chained request parameter lists 55,69
OPTCD subparameter, in AMP parameter 32
options
  exit routines 26
  types of access 21
  types of data sets 16
OR sign (|), in notational conventions 3
OUT option, in MACRF operand 49
overlapping processing, example 125

P

parameter list
  exit list 41
  specified in EXLST macro 51
  specified in GENCB macro 63
  of GENCB, MODCB, SHOWCB, or TESTCB macro 159
  estimating size for list form of macros 160
  sharing among macros 164
  request parameter list 41
parentheses, in notational conventions 4
partial key (generic key) 22
PASS subparameter, in JCL 30
PASSWD operand
  in ACB macro 48
  in FIELDS operand 77
  in GENCB macro 61
  in MODCB macro 71
  in TESTCB macro 86
  interaction with MACRF 48,61
passwords
  field containing password for OPEN 34
  levels of authorization 34
path 19
PATH option, in OPENOBJ operand 88
physical-error analysis
  ISAM interface 132
  SYNAD exit routine 143
physical-error function codes 97
physical-error message 100
physical-error return codes from request macros 96
PL/I language 129
POINT macro 122
  example 122
  relative to GET-previous processing 22
  restriction 123
positioning, concurrent
  additional buffer required for 49
  giving up a position 127
positioning for sequential access
  by entry sequence 25
  by key sequence 22,122
  by relative record number 23
  done by POINT macro 122
preparing to open a data set 29
prime keys 20
PRIVATE subparameter, in JCL 30
processing options 21
  direct access 21
  identifying record by key, address, or relative record
  number 21
  overlapping processing 125
  providing exit routines 26
  specified at assembly or execution 21,41
processing types 21-25
  (see also keyed access and addressed access)
  specifying 41
programming languages 129
program, reentrant 159
PSW condition code, set with TESTCB 85

publications
related 5
required 5
VSAM and Access Method Services 4
punctuation, in notational conventions 4
PUT macro 110
examples 111
PUTIX macro 96

Q
QISAM (queued indexed-sequential access method) 130
queued indexed-sequential access method (QISAM) 130

R
random access (see direct access)
RBA (relative byte address)
changeability in control area and control interval
   splits 146
changeability in key-sequenced data set 17
definition 16
example, recording when loading records 112
unchangeability in entry-sequenced data set 18
RBA operand
   in FIELDS operand 83
   in TESTCB macro 92
reading a record
   addressed 25
   keyed 22
   skipping 23
read-only password 34
RECFM subparameter, in AMP parameter 32
RECLLEN operand
   in FIELDS operand 83
   in GENCB macro 68
   in MODCB macro 74
   in RPL macro 55
   in TESTCB macro 92
record
   alternate-index 19
   format with ISAM interface, specified in RECFM
      parameter 138
   length, specified in GENCB 68
   length, specified in RPL 55
   relative 17
   spanned 16
recording data set errors 145
reentrant program
   form of GENCB macro used to code 159
   form of MODCB macro used to code 159
   form of SHOWCB macro used to code 159
   form of TESTCB macro used to code 159
register notation
   in CLOSE macro 37
   in GENCB, MODCB, SHOWCB, and TESTCB
      macro 164
   in OPEN macro 33
   in request macros 102,110,120,122,123,127
relative byte address (see RBA)
relative record data set
   compared with entry-and key-sequenced data sets 18
defined 16
   keyed access 22,23,15
relative record number
   defined 17
   used as a key 17
release position, example 127
remote terminals 27
REPL attribute, in ATRB operand 87
request macros 95
   CHECK 123
   ENDRQ 127
   ERASE 119
   GET 102
   logical-error return codes from 95
   physical-error return codes from 100
   POINT 122
   PUT 110
request parameter list
   chaining 55,68
   changing 73
   defining with the RPL macro 52
   displaying fields of 82
   fields of, displayed with the SHOWCB macro 82
   generating with the GENCB macro 65
   modifying 73
   testing a field of 92
requesting access to data 95
resource sharing 44
restart 32
restrictions in the use of the ISAM interface 139
RETLN subparameter, in JCL 30
retrieving a record
   addressed 25
   keyed 22
   skipping 23
retrieving an index record 96
return codes
   checking, example 124
   from alternate index upgrade requests 97
   from CLOSE macro 38
   from GENCB, MODCB, SHOWCB, and TESTCB
      macros 42
   from OPEN macro 35
   from request macros 95
reusable data set 16
   restrictions 16
   specifying in ACB macro 49

S

SCHBFR macro 149
SCRA option, in CRA operand
  in ACB macro 47
  in GENCB macro 60
  in MODCB macro 71
  in TESTCB macro 87
restriction 47,60/71
search argument
  full key 22,56
  generic (partial) key 22,56
  RBA 17
  relative record number 23
searching catalogs, order of 31
security of data
  authorization routine 147
passwords 34
security-authorization record, user 147
security-verification routine, user 147
SEQ option
  in MACRF operand 49
  in OPTCD operand 56
sequential access
  addressed 25
  keyed 22
  positioning 22,122
  skipping 23
SER subparameter, in JCL 30
service program (see Access Method Services)
shared resources 44
sharing control blocks
  based on DDNAME 44
  based on DSNAME 44
sharing parameter lists among GENCB, MODCB, SHOWCB, and TESTCB 164
shortening a record
  changing RBAs 17
  entry-sequenced data set 18
SHOWCAT macro 149
SHOWCB macro
  examples 79,81,84
  execute form 163
  generate form 163
  list form 163
  operand notation for 167
  return codes from 42
  used to code a reentrant program 159
  used to display fields of
    access-method control block 75
    exit list 80
  request parameter list 82
SHR subparameter, in JCL 30
SIS option, in MACRF operand 49
skip-sequential access
  examples 103,113
restriction with GET-previous 22
SKP option
  in MACRF operand 49
  in OPTCD operand 56
SPAN attribute, in ATRB operand 87
spanned records 16
SSWD attribute, in ATRB operand 87
STEPCAT JCL statement 29
STMST operand
  in FIELDS operand 78

in TESTCB macro 86
storage requirements, I/O buffers 46,47,59
storing a record
  addressed 25
  keyed 22
  skipping 23
storing an index record 96
string extension, dynamic 45,49
STRNO option, in FIELDS operand 77
STRNO operand
  examples 47
  in ACB macro 49
  in FIELDS operand 77
  in GENCB macro 61
  in MODCB macro 71
  in TESTCB macro 86
STRNO subparameter, in AMP parameter 33
ISAM interface 138
substituting processing parameters by way of JCL 32
summary of amendments 13
summary of macros used to gain access to data 149
suspending processing, example 126
SYN option, in OPTCD operand 56
SYNAD exit routine
  analyzing physical errors 143
  coding 143
  contents of registers at entry 144
  physical-error message 100
  specifying the exit with EXLST macro 51
  using ISAM interface 138
  contents of registers at entry 133
  example 141
SYNAD operand
  in EXLST macro 51
  in FIELDS operand 80
  in GENCB macro 63
  in MODCB macro 72
  in TESTCB macro 90
SYNAD subparameter, in AMP parameter
  with ISAM 139
  with VSAM 33
SYNADAF macro, in ISAM program 133
synchronous processing
  specified in MODCB macro 74
  specified in RPL macro 56
system catalog, in order of catalog search 31

T

T (in TYPE operand in CLOSE macro) 38
temporary CLOSE macro 38
terminals 27
terminating a request before completion 127
TESTCB macro
  examples 88,89,91,94
  execute form 163
  generate form 164
  list form 163
  operand notation for 171
  return codes from 42
  setting PSW condition code 85
  used to code a reentrant program 159
  used to test a field of
    access-method control block 85
    exit list 90
  request parameter list 92
testing a control block
access-method control block 85
exit list 90
request parameter list 92
Time Sharing Option (TSO) 27
TRACE subparameter, in AMP parameter 33
tracing 33
transactions, journalizing 146
TRANSID operand
in GENCB macro 68
in MODCB macro 74
in RPL macro 55
in TESTCB macro 92
TRANSID option, in FIELDS operand 83
translating ISAM requests 130
TSO (Time Sharing Option) 27
TYPE operand, in CLOSE macro 38

U
UBF option, in MACRF operand 49
UCRA option, in CRA operand
in ACB macro 47
in GENCB macro 60
in MODCB macro 71
restrictions 47,60,71
UIW option, in FIELDS operand 78
underlining, in notational conventions 3
unique keys 19
UNIT parameter, in JCL 30
UNQ attribute, in ATRB operand 87
UPD option, in OPTCD operand 56
update password 34
updating a record, example 116
(see also storing a record, lengthening a record, and shortening a record)
upgrade set 20
status following request that fails 97
upper case, in notational conventions 4
user buffering 49
user catalog
JCL 29
order of search 31
specified for job 29
specified for job step 29
user security-authorization record 147
user security-verification routine 147
contents of registers at entry 147
using passwords to authorize access to data 34
USVR (user security-verification routine) 147
utility program (see Access Method Services)

V
verification routine, user-security 147
VOLUME parameter, in JCL 30
